85. *d. Erysipelatous Ophthalmia* — *Conjunctivitis Erysipelatosa*. — The inflammation of the conjunctiva attending erysipelas is preceded by redness and great swelling of the lids. In rarer instances, it follows upon an erysipelatous affection of the throat and posterior nares; and it is, in cases of severe affection of the face or scalp, often attended by much inflammation of, and effusion into, the cellular tissue surrounding the globe. It is most common in persons past middle age, or of a cachectic habit of body. The conjunctiva of the lids and ball is more or less injected; that of the latter often rises in soft yellowish red vesicles around the cornea, and occasionally it is affected in nearly a similar manner to the *pustular variety* already described. In some cases the redness partakes of a yellow tint, and in others of a livid or brownish hue. The eye has a watery appearance, and the cornea is often hazy from the fluid collected on its surface, but it is seldom otherwise affected. As the disease subsides, the copious lachrymation generally present is diminished, but the organ regains its natural state very slowly. The constitutional disturbance is very severe in this variety. (See Erysipelas.) The *Treatment* consists of local depletions, which, however, should be cautiously practised; of emetics, purgatives, blisters, diaphoretics; and of opening the vesicles that form, with the point of a lancet. In an advanced stage, tonics, and other remedies suited to particular cases, are requisite.

ii. INFLAMMATION OF THE PROPER EXTERNAL TISSUES OF THE EYE. — A. COMMON INFLAMMATION OF THE EXTERNAL TUNICS. SYN. — *Ophthalmia externa Idiopathica*, BEER; *Ophthalmia Sclerotica*, VETCH; *External Inflammation of the Globe*, LAWRENCE; *Co-*

tarrho-rheumatic Ophthalmia, MACKENZIE, — *Phlegmonoid Sclerititis*. — *a. Acute*, — *b. Sub-acute*, — and *c. Chronic*.

86. CHARACTER. — *Redness of the external proper coats of the eye, with pain, intolerance of light, increased lachrymal discharge, and febrile disturbance.*

87. *a. Symptoms and Course*. — Simple or common inflammation of the eyes of persons otherwise healthy may originate in the conjunctiva or sclerotic; but, when severe in either, it generally extends to the other, and also to the cornea. It frequently also appears almost coëtaneously in both coats; and it presents every grade of severity. The external redness usually begins on the anterior part of the globe, forming a zone around the cornea, and arises from small vessels advancing from the posterior part of the sclerotic to the part adjoining the cornea. As the inflammation proceeds, the redness becomes uniformly diffused in the sclerotic, and is of a pink, rose red, or almost violet hue. In the more severe cases, the distended vessels are seen under the conjunctiva, occupying the whole surface of the sclerotic, and generally running in nearly straight lines from behind forwards. When the inflammation is seated in both this coat and the conjunctiva, the difference as to tint and situation between the vessels of each is very remarkable. The patient complains of stiffness and dryness of the eye, is intolerant of light, and feels a burning or aching pain, with a sense of tension, or pressure, or of dust in the eye (*Xerophthalmia*, or *Oph. Sicca*). The pain usually increases, and extends to the orbit and corresponding side of the head; the intolerance of light becomes greater; and the pupil is contracted. As the disease advances, the conjunctiva participates, its vessels are distended, and the cornea becomes dull, but not, at first, nebulous or opaque. In more violent cases, this membrane acquires a bright red colour, or even passes into a state of chemosis. At the same time pain and fever increase, the inflammation extends to the lids, and the cornea assumes a greyish hue. The dryness characterising the commencement of the complaint gives place to lachrymation, which is increased on opening the eye to the light, or moving it.

88. *b. The Effects* that present themselves, as the disease proceeds in an *acute form*, are observed chiefly in the cornea, and occasionally also in the iris. — The former becomes either vascular, and red or reddish brown, or greyish, and subsequently white, cloudy, and yellow, as if pus were infiltrated into its substance. It often afterwards *ulcerates*; the ulcerations sometimes extending into the anterior chamber, and causing the usual consequences of this change. *Adhesion*, also, of the iris to the cornea may occur either with or without ulceration of the latter, but always with more or less *opacity*. When the cornea presents only the first stage of change, is greyish, cloudy, or white, ulceration may be prevented, or arrested if it have begun, by suitable treatment, and if it have not occurred, the cornea may regain its natural appearance.

89. *c. The sub-acute and chronic states* of the complaint are characterised by less severity, but longer duration, of the symptoms described above, particularly those depending upon the

affection of the sclerotica. They often follow the neglected or inactively treated acute disease. In these cases, the conjunctiva of the eyelids is somewhat irritated or inflamed. The eyes are painful on exertion, or exposure to much light; and the lachrymal discharge is thereby increased. In the more severe and protracted attacks, the transparency of the cornea and vision are more or less impaired. Although the chronic often thus supervenes upon the acute complaint, owing to neglect, to errors in diet, to indulgences in spirituous liquors, or to exertion of the organ, when the inflammation has been only partially subdued; yet, in persons of a cachectic habit of body, it may be the primary affection. In delicate or unsound constitutions, also, the complaint very frequently assumes a sub-acute or chronic form from the commencement, and continues long, until an increase of certain of the symptoms alarm the patient.

90. *d. Diagnosis.*—Inflammation of the external proper tunics of the eye is distinguished from that of the conjunctiva, by the redness commencing in the sclerotica, in the vicinity of the cornea, and extending backwards in the direction of the orbit, and only consecutively to the conjunctiva; inflammation of this membrane usually following an opposite course, and extending to the sclerotica only when it advances to the cornea. The discharge being lachrymal, and not mucous or purulent; the severity of the pain, and the intolerance of light; the situation and direction of the injected and enlarged vessels; the peculiar tint presented by the inflamed sclerotica; and the more frequent affection of the cornea; are circumstances sufficiently diagnostic of the complaint. The natural state of the pupil and iris, and the unimpaired vision, distinguish it from internal ophthalmia.

91. *e. The Prognosis* entirely depends upon the degree in which the cornea is affected.—As long as this part is unchanged, or if the lesion of it be but slight, a favourable opinion may be given. The case becomes serious, when the complaint occasions chemosis, and a greyish or whitish alteration of the cornea; and still more so, if matter be formed in it. In this case, ulceration will be inevitable; and the effect of ulceration or opacity upon the sight will depend upon their extent and situation in reference to the pupil.

92. *f. Treatment.*—*a. In the acute form.*—*The predisposing and exciting causes* (§ 4, 5, 6.) to which the complaint may be referred, should be completely removed. The organ should next be protected from exertion, and from light and air. If one only be affected, the other should not be used, nor exposed to injurious influences. These measures, in slight cases, may be sufficient to cure the complaint; and have succeeded when further treatment could not be resorted to. But others should be employed, particularly in severe cases; and still more so in such as are violent, or are attended by affection of the cornea. Even in mild attacks, active treatment should not be withheld, as, even in these, neglect may be followed by serious results as respects the sight. *Bloodletting*, general or local, can rarely be dispensed with. The former ought always to be preferred when the complaint is attended by febrile disturbance, and should be carried sufficiently far to impress the circulation. It will be most

advantageous if practised in the manner advised in the article BLOOD (§ 64.), and followed by the means there recommended (§ 65.). In milder cases, or in more delicate persons, or after venesection, *local bleeding*, either by cupping on the nape of the neck, or behind the ears, or on the temples, may be directed; or leeches applied on the two latter situations. Mr. LAWRENCE advises them to be placed upon the lids, to the number of from twelve to twenty-four in the case of an adult. *Scarification* of the conjunctiva, is disapproved of by him, although recommended by some writers. WELLER advises it when chemosis is present. In this form of ophthalmia, the modes of depletion now mentioned are the most appropriate. *Cupping* in many cases may supersede venesection; as a sufficient quantity of blood may be taken in this way from either of the situations just named, for the exigencies of almost any case.

93. *Purgatives*, low diet, *refrigerants*, when the febrile excitement is considerable, and *diaphoretics*, are the next most important measures. *Calomel* and *James's powder*, either with or without *opium*, at bed time; cathartics in the morning, and mild diaphoretics and diluents during the day; are generally appropriate. If vascular excitement continue notwithstanding, an antimonial *emetic* should be prescribed; or it may follow the depletion, and precede the exhibition of a full dose of calomel and purgatives. In the more violent or protracted cases, *tartar emetic* may be given so as to keep up a continued nausea. When costiveness is present, or purgatives act insufficiently, drastic or terebinthinate *emenata* are requisite. If the free use of calomel, after the depletions, affect the mouth, the occurrence should be viewed as favourable; complete recovery being thereby accelerated, and the ill effects of the disease on the cornea prevented. *Colchicum* has been noticed in this complaint by several writers; and is serviceable either in the form of powder with calomel, or in aperient mixtures. It is most efficacious after the bowels have been fully evacuated. When the inflammation has been nearly removed by the preceding remedies, blisters on the nucha or behind the ears, and warm *pediluvia* at bed time, are useful in preventing a relapse or the passage of the complaint into a chronic state.

94. The *local means*, in addition to bleeding, consist chiefly of *cold*, *warm*, *emollient*, and *astringent* applications. The choice of these is a matter of some difficulty; but when the disease is only commencing, or when the patient complains of great heat or burning in the eye, and experiences relief from *cold epithems*, then any of the various modes of applying cold may be adopted. If, however, the complaint be advanced, or if cold occasions an aching or chilling sensation, warm applications or *fomentations* should be preferred. It has been doubted by Mr. LAWRENCE and some other writers, whether such as are *emollient* and *marcotic* be at all superior to those which are more simple. The former have been recommended principally by Continental, the latter by British, physicians. The doubt has arisen chiefly from a physiological notion long entertained, although the grounds on which it is founded admit of a ready refutation. An intimate observation of phenomena—the only legitimate

experience — should alone decide the question. Although my experience in this matter has necessarily been limited of late years, yet have I seen enough even of this complaint, to convince me that fomentations with emollient and anodyne substances are superior to those which are simple — which consist only of warmth conjoined with humidity. Therefore, when the pain and intolerance of light are great, the disease somewhat advanced, or even established, warm emollient and anodyne applications ought to be preferred. SCARPA directs mallows boiled in fresh milk as a fomentation; or emollient and anodyne vapours, to be conveyed to the eye through an inverted funnel. Mr. MACKENZIE directs opiate frictions of the forehead and temples, and the eye to be kept under the influence of *belladonna*. Fomentations with a decoction of poppy-heads and camomile flowers, or marsh-mallows; and the vapour of warm water, to which camphor and the watery extract of opium have been added; are generally beneficial in the circumstances just stated. Dr. SMITH remarks, that when the pain was not alleviated by bloodletting or by fomentations, much and lasting relief was procured by exposing the eye, twice or thrice daily, to the steam arising from the following mixture brought to a boiling heat. It is now eighteen years since a nearly similar combination, but with much more opium and camphor than is here ordered, was prescribed by me with great relief in a case of the disease.

No. 219. — R. Mist. Camphoræ ʒij; Tinct. Opii ʒ ss; Liq. Ammon. Acet. ʒij; Aq. Rosar. ʒiv. M.

95. β. *The sub-acute and chronic states*, especially the former, sometimes require either *venesection*, or full *cupping*, particularly in young or robust persons. In most instances, *leeches* should be applied to the vicinity of the eye; and sometimes either they or cupping ought to be repeated oftener than once. *Purgatives* should be freely employed; and, if the tongue be loaded, and the evacuations offensive, an *emetic* should precede them. Great attention ought to be paid to the *diet*; and animal food must be taken only in small quantity or nearly relinquished. *Counter-irritation* is generally beneficial; and either open blisters, pustulation by means of tartar emetic, setons, or issues, should be directed to the nape of the neck, behind the ears, or to the temples. During treatment, the bowels should be freely opened by stomachic purgatives, particularly if the tongue be loaded, and the discharges morbid; and the regimen as well as the diet rigorously restricted. If the above treatment have been actively employed, the complaint will be removed, without the necessity of resorting to *astriking* or *stimulating applications*. But, in neglected cases, they are sometimes very beneficial, especially if the affection of the conjunctiva be considerable, after the above measures have been appropriately prescribed, and when the complaint is far advanced, or in a chronic state. The *vinum opii*, dropped into the eye, was recommended by Mr. WARE; and is suited chiefly to chronic cases. The liquid laudanum of SYDENHAM (F. 729.), or preparations similar to it, may also be applied. The collyrium praised by CONRAD, and which consists of one grain of bichloride of mercury dissolved in six ounces of rose water, with the addition of a drachm of

mulilage of quince-seeds and half a drachm or a drachm of SYDENHAM'S laudanum, is often of service. Several other applications, some of them much more astringent than the above, have been recommended; but they are undeserving of particular notice. The astringent ointments, and solutions found so beneficial in the treatment of conjunctivitis (§ 16. 50.), may also be employed in the chronic states of this complaint, particularly under the circumstances just specified.

96. B. RHEUMATIC, CATARRHO-RHEUMATIC, AND ARTHRITIC OPHTHALMIA. SYN. — *Ophth. Rheumatica et Arthritica*. — *Sclerotitis Rheumatica et Arthritica*. — *Inflammation of the External proper Tunics in Rheumatic and Gouty Constitutions*.

97. a. *The Rheumatic modification of ophthalmia*. — *Sclerotitis Rheumatica or Atmospherica* of MACKENZIE — is seated in the external proper tunics of the eye, as in the common, or phlegmonoid, variety just described. The conjunctiva is only slightly affected; but the inflammation sometimes extends to the *iris*, or *cornea*, or to both, but generally in a slight degree. It is commonly caused by cold, or currents of air striking the eyes of persons of a rheumatic diathesis. It is not a common affection, and seldom arises from metastasis.

98. b. *Symptoms and Course*. — A stinging or tearing pain is complained of in the eye, increased by heat and by a warm bed, and extending to the orbit and adjoining parts of the head and face. The sclerotic is of a rose red, and shines through the conjunctiva, which is more injected than usual. There is an increased flow of tears, aggravated by changes of temperature. The pain subsequently becomes more dull and aching, extends with greater severity to the neighbouring parts, and lachrymation is augmented. The intolerance of light, which was only slight, is afterwards felt only in a strong light. Dullness or haziness of the cornea is frequently observed, but is seldom followed by any serious change. Sometimes *phlyctenulae* appear in the conjunctiva oculi and cornea, but they do not often pass into ulceration. The biliary and intestinal functions are more or less disordered; and febrile disturbance is commonly present. The *severity and duration* of an attack vary very much. Slight cases soon subside; but severe attacks may give rise to *iritis*, which is, however, rarely acute, unless the disease be neglected, when it may go on to effusion of coagulable lymph. Rheumatic scleritis is not attended by affection of the lids, nor by chemosis: it does not give rise to suppuration, and rarely to ulceration, the ulcers being small or peculiar, and healing readily; and it sometimes lapses into a very chronic, slight, or recurring form.

99. c. *The Catarrho-rheumatic ophthalmia* of some writers does not differ materially from the common or phlegmonoid inflammation of the proper external tunics (§ 86.), being seated in the sclerotic and conjunctiva. It is usually caused by cold, and atmospheric changes; and in the rheumatic diathesis, very nearly approaches, or merges into, the rheumatic form; the only difference being in the greater affection of the conjunctiva, and in the consequent manifestations of certain catarrhal symptoms.

100. d. *Arthritic Ophthalmia* — *Sclerotitis Arthritica*. — *Arthritic external Ophth.* — or inflam-

mation of the external proper coats occurring in the gouty habit, is oftener attended by *iritis*, than the rheumatic variety; but *iritis* is frequently observed in gouty persons without sclerotitis. Sometimes gouty inflammation of the sclerotica is accompanied with an *erysipelatous form of conjunctivitis*, which BEER has seen to follow the suppression of gout in the feet by cold. The progress of this modification of external ophthalmia, in its early course, is similar to the rheumatic, when it is confined chiefly to the sclerotica; but when the conjunctiva is also affected, it hardly differs from the *erysipelatous variety* already described (§ 85.). When the external proper tunics are the parts attacked by the gouty affection, pain of the eyeball is very acute, and darts in the course of the facial nerves, and is usually preceded by a pricking sensation. A flow of acrid tears takes place. The sclerotica around the cornea becomes of a rose red colour, which is less vivid towards the circumference of the globe; and does not extend to the cornea, but leaves, immediately around it, as a pathognomic symptom, a narrow bluish white ring. The conjunctiva oculi soon partakes in the redness and increased vascularity, and is subsequently congested and varicose; the bright redness being changed to a dirty grey or violet colour. Arthritic ophthalmia runs a shorter or longer course; is milder in dry weather and in summer, than in wet weather and in winter; and is aggravated by, or accompanied with, derangements of the digestive organs. It is generally associated with *iritis*, but arthritic *iritis* may exist without the external proper tunics being materially affected. (See *Arthritic Iritis*, § 134.)

101. *e. The Prognosis in rheumatic ophthalmia* is favourable, unless phlyctenæ have formed and occasioned small ulcers; or *iritis* have supervened. But, in young or healthy persons these ulcers seldom leave permanent specks or cicatrices behind them. *Arthritic ophthalmia* is generally a more serious complaint than the rheumatic; and if it be attended with *iritis*, the association is much more dangerous to vision. It is also frequently accompanied with affection of the internal parts.

102. *f. Treatment.* — *a.* In *rheumatic ophthalmia*, general bloodletting is rarely necessary, but local bleedings are often serviceable. Calomel conjoined with camphor, James's powder and opium, at bedtime; and stomachic purgatives in the morning, assisted by *terebinthinate enemata*; are very beneficial in this variety. *Colchicum* is often of use, in conjunction with aperients and alkaline or magnesian carbonates: but it should not be given in the very large doses mentioned by some surgical writers. Its effects ought always to be carefully watched. After the bowels have been freely evacuated, the *tinctura colchici composita*, or a combination of the powder and camphor, should be preferred, particularly in delicate or aged persons. Warm applications and *fomentations* are most appropriate in this variety; and the steam of boiling water, containing camphor and tincture of opium, generally affords relief. *Diaphoretics* and warm *pediluvia* are also useful. If *iritis* has come on, *calomel*, in the combinations just stated, is especially indicated. If the mouth be affected by it, the good effects will be greater and more permanent.

103. Besides the above remedies, others may be employed in *chronic* or obstinate cases: as the compound decoction of guaiacum, or the decoction of bark, with the compound tincture of colchicum; quinine with or without the powder of colchicum; FOWLER'S arsenical solution; PLUMMER'S pill and aperients; antimony, or ipecacuanha with camphor and opium; vinous or spirituous preparations of opium dropped into the eye; frictions in the vicinity of the eye with opium or belladonna, or with both, to alleviate pain and dilate the pupil; and counter-irritation by blisters or the tartar emetic ointment behind the ears or on the temples. If phlyctenulæ form, and run into small ulcers, *astringent* and *stimulating applications* will be necessary. In cases presenting much biliary or gastric disorder, an *emetic* will be useful; and, under any circumstances, change of air, regulated diet, attention to the biliary and intestinal functions, and the repose or moderate exercise of the organ will be of essential service.

104. *β.* The *treatment of arthritic ophthalmia* does not materially differ from that recommended in the rheumatic form. Warm stomachic purgatives, with full doses of the alkaline carbonates, and the compound tincture of colchicum; mustard pediluvia; blisters behind the ears; and dry warmth applied to the eye; and anodynes rubbed upon the temples and eyebrows; are more particularly indicated in this variety. If *iritis* supervene, the means directed hereafter in *Arthritic Iritis* must be resorted to.

105. *C. INFLAMMATION OF THE CORNEA. SYN. — Corneitis Ceratitis, JUENGEN; Keratitis, ROSAS.* — *Corneitis* may be either *acute* or *chronic, primary* or *consecutive*. Inflammation may commence in the cornea, and be confined to it, or extend to the sclerotica and conjunctiva, and sometimes to the iris, or it may begin in either of these tunics, and advance to the cornea. *Corneitis* often comes on, in this latter form, in most of the varieties of ophthalmia which have been considered; and presents either the *acute, sub-acute, or chronic* states, especially the latter. The *primary form* of *corneitis*, therefore, remains to be noticed. It is much less common than the *consecutive*, and is most frequently *caused*, especially its *acute, or severe states*, by external injuries, and by foreign bodies, or acrid substance brought in contact with the cornea.

106. *a. Acute Corneitis* may be of various degrees of severity in different persons. In some, there is but little local uneasiness beyond irritation on motion; whilst, in others of a full habit, or who are laboriously occupied, exposed to heat, or addicted to intoxicating liquors, the inflammation is most intense, and rapidly extends to the sclerotica and whole anterior chamber, with *hypopyon*. The more severe states usually commence with a pink zone in the sclerotica, around the cornea, which loses its transparency, and becomes minutely injected with delicate-coloured vessels, particularly at its circumference, and dull, turbid, or cloudy. If the inflammation be excited by a foreign body, ulceration takes place around it. If the disease be not soon arrested, the pink zone assumes a deeper tint, and extends further in the sclerotica; the cornea is rendered more opaque, and suppurates; and the chambers of the aqueous humour are involved. When the

cornea is penetrated either by ulceration or supuration, the aqueous humour escapes, the iris and cornea coming in contact. When the wound in the cornea is small, it unites by adhesion, and the aqueous humour is soon reproduced; but when it is large, prolapsus of the iris often results.

107. *b. Sub-acute and chronic Corneitis* is common in young persons of a fair complexion and delicate constitution. The cornea loses its transparency, presents a dull grey colour, or becomes hazy, nebulous, or nearly opaque; the opacity commencing at the circumference, and gradually but unequally extending. The nebulous and opaque spots are sometimes yellowish, as if matter were formed: and the surface loses its polish, and seems rough. The circumference of the cornea is minutely injected with a multitude of very fine vessels, which impart to it a reddish brown tint, and occasionally elevate it somewhat. The conjunctiva often retains its natural paleness, but the sclerotica is minutely injected, particularly around the cornea. As the brownish red tint of the circumference of the part increases, the opacity in its centre becomes greater, and vision more affected. There is generally much intolerance of light, notwithstanding the diminished transparency of the cornea, owing to affection of the sclerotica. A *partial form of corneitis*, which is generally of very long duration, is sometimes met with. Inflammation commences in one or two spots at the circumference of the cornea, with pain of the eye, and nebulosity; others being affected in succession. Redness is first observed in the sclerotica, in one or two points; and minute vessels extend from these into the cloudy spots in the cornea; more or less of which may become thus affected, or entirely opaque.

108. Although the severe and acute grades of corneitis often run into supuration or ulceration, the slighter or more chronic states do not terminate in this manner, excepting in sub-acute cases, where partial or circumscribed points of supuration may occur. The more severe grades are attended by much pain in the eye, temples, and forehead; with tension of the organ, white tongue, and febrile disturbance, particularly at an early stage; and they often pass into the slighter and chronic states; but the latter also occur primarily. Chronic corneitis presents much less febrile disorder than the acute, and often continues for several months, or remits. The inflammation sometimes extends to the iris, occasioning adhesion of its margin to the capsule of the lens.

109. *c. Scrofulous Corneitis*—*Corneitis scrofulosa*.—Inflammation of the cornea in scrofulous habits has been minutely described by Dr. FROBER and Mr. MACKENZIE; but its local characters do not differ from those of the sub-acute and chronic forms noticed above (§ 107, 108.), excepting that it is more obstinate, and more liable to return. It is sometimes unattended by redness of the sclerotica; and the pain is not considerable. It is most common about the period of puberty, and is occasionally connected with amenorrhœa in the female, and with swollen lymphatic glands. In the more obstinate cases, increased secretion of the aqueous humour, and consequent enlargement of the anterior chamber, occasionally supervene.

110. *d. Treatment*.—*a. Acute corneitis* requires active depletory and other antiphlogistic measures. *Cupping* behind the ears or on the tem-

ples is always necessary. *Purgatives*, and afterwards *calomel* with *James's powder*, and occasionally with *apium*, until the mouth is affected, are beneficial, especially if the iris be inflamed. In the more obstinate and chronic cases, cupping, or the application of a number of leeches to the vicinity of the eye, should be repeated oftener than once, and be followed by open *blisters*, *setons*, or issues. Mr. LAWRENCE advises issues to be inserted in the temples. *Astringent* and stimulating applications to remove the opacity are generally injurious. Warm *fomentations* are more serviceable, particularly with emollient and anodyne substances. *Emetics*, if the digestive organs be loaded; and *diaphoretics*, assisted by warm pediluvia, if the skin be dry, and fever present; are also useful.—*β*. The *scrofulous variety*, especially its more chronic states, is benefited most by sarsaparilla, sulphate of quinine, decoction of bark with liquor potassæ, the compound myrrh mixture, the iodide of potassium, and by small doses of the bichloride of mercury in tincture of bark.—As this variety often continues many months, perseverance in the use of these means, and changes from the one to the other, a dry warm air, and change of air, with attention to the state of the digestive organs, and a carefully regulated diet, are most requisite.

111. INFLAMMATION OF THE INTERNAL PARTS OF THE EYE. SYN.—*Internal Ophthalmia*, *Ophthalmitis Interna*, Auct. var.

111. DEFIN.—*Inflammation of one or more of the internal tissues of the eye, occurring either primarily, or consecutively of external disease, and attended by impaired vision, and frequently by constitutional disorder.*

112. In diseases of the internal eye, artificial dilatation of the pupil is necessary both to the investigation of their nature and extent, and to their treatment. Mr. LAWRENCE has given a learned account of the agents by which dilatation may be accomplished. Various narcotic vegetables possess this power, but *belladonna* in the highest degree. The tincture, extract, decoction, infusion, or powder of this plant may be employed for this purpose, either internally, or dropped into the eye, or rubbed on the brow or temple. *Hyoscyamus* is the next powerful substance. An aqueous solution of the extracts of either may be rubbed or placed upon the eyelids or parts in the vicinity, and washed off after remaining for about an hour; or it may be dropped into the eye, when a speedy and certain effect is desired.

i. INFLAMMATION OF THE ANTERIOR CHAMBER. SYN.—*Inflammation of the Capsule of the Aqueous Humour*, WARDROP; *Aquo-Capsulitis*, MACKENZIE; *Kerato-iritis*, ROSAS; *Inflammation of the Anterior Chamber*, LAWRENCE.

113. CHARACT.—*Diffused muddiness, or mottled appearance of the cornea, dimness of vision, fullness and tension of the eye, dullness of the iris, slightly contracted pupil, headach, white tongue, and fever.*

114. Inflammation of the membrane of the aqueous humour is often consequent upon the varieties of ophthalmia already described; but is also a primary disease, and is most common in this form among children. It cannot be considered, even when primary, to be confined to the anterior chamber, or to this membrane. The

posterior chamber, the cornea, and iris, evidently, are also affected more or less. External inflammation involving the cornea may extend to the anterior chamber and to the iris; or inflammation may commence in the latter, and spread over this cavity to the cornea, and either adhesion of the iris to the cornea, or hypopyon, be produced. Primary inflammation of this membrane presents the usual phenomena of inflamed serous surfaces; viz. effusion of albuminous or coagulating lymph, or of a serous fluid, and very rarely of pus; the first of these sometimes becoming organised into morbid adhesions.

115. *A. Symptoms.* — The anterior chamber is cloudy; the iris becomes dull and dark, its surface assumes a reddish brown tinge, the reddish tint being most evident in light eyes; and the pupil is somewhat contracted. The cornea loses its transparency, becomes nebulous or mottled, sometimes with an ulcer in its surface. There is but little external redness, excepting a pink zone around the cornea. An effusion of whitish or yellowish matter takes place in the anterior chamber; and the patient complains of pain and aching in the eye and forehead, of fulness or tightness in the organ, and of intolerance of light, especially early in the complaint; these symptoms subsiding at more advanced periods. Its progress in children is not rapid. Mr. WARDROP considers the opacity to be seated in the internal surface of the cornea; and that it arises from a number of round specks, which give a mottled appearance to this part, particularly in adults. He also believes the effusion into the chamber, which has been generally considered pus, to be albuminous, and similar to that which causes adhesions, but not coagulable.

116. *B. Hypopyon* — or the presence of a yellowish matter in the anterior chamber, resembling, and usually called, *pus*, and attending or consequent upon inflammation — accompanies the affection now under consideration. But it more frequently supervenes, in the advanced course of inflammation of the external coats, from the bursting of an abscess in the cornea. It may also occur from iritis, particularly if an abscess of this part burst into the anterior chamber. Inflammation, however, of the membrane of this chamber, is common to all these affections, in a consecutive or associated form. When matter is effused behind as well as before the iris, it constitutes *empyema oculi*, or suppuration of the eye. Various forms and divisions of hypopyon have been devised by BEER, RICHTER, BENEDICT, and JUENGEN; but they do not deserve notice, as they lead not to any practical result, and as this is not a peculiar disease, but the result of inflammatory action consecutively or primarily affecting the membrane of the chamber, and tissues surrounding it. Whether the matter in hypopyon be pus or an albuminous fluid, it seems to sink to the bottom of the aqueous humour; but, in some instances, it appears as if heaped up or in lumps; and, in this case, a minute admixture of blood sometimes is seen in it.

117. *C. Treatment.* — *a. Inflammation of the anterior chamber* is readily controlled by local bleedings, purgatives, and calomel with James's powder, given twice or thrice a day. Mr. WARDROP has strongly advised puncture of the cornea, to evacuate the aqueous humour, in this and some other

affections attended by inflammation of the membrane secreting this humour, after suitable treatment has been employed; and MACGREGOR, MUELLER, LANGENBECK, and BENEDICT speak favourably of it, as a measure calculated to prevent rupture of the cornea in purulent ophthalmia. Mr. LAWRENCE, who takes a candid view of the matter, thus remarks; — "I have tried it in some instances, but with so little benefit that I have not been induced to persist in the practice; and I have been the less inclined to do so in severe inflammations, because the ordinary antiphlogistic treatment enables us to control them."

118. *b. Hypopyon*, being an attendant, rather than a termination, of inflammation beginning in or extending to the anterior chamber, requires the antiphlogistic treatment recommended in the acute forms of ophthalmia. The only question is, whether or not the cornea should be punctured to evacuate the matter collected behind it. Puncture or incision has been advised for this purpose by WARE, RICHTER, BENEDICT, LANGENBECK, and WARDROP. BEER at one time directed it, but afterwards reprobated it. Dr. MONTEATH and Mr. MACKENZIE recommend its performance in every case in which the chambers are completely filled; as they consider absorption in such not to be depended upon, and dread the bursting and destruction of the eye. SCARPA and LAWRENCE, on the contrary, prefer active antiphlogistic treatment; as they consider that the operation aggravates the inflammation, and that when the inflammation is removed by judicious and energetic means, the effusion will be rapidly absorbed. In this opinion I entirely concur.

ii. INFLAMMATION OF THE IRIS. SYN. — *Iritis*, SCHMIDT.

119. CHARACT. — *Fine vessels running in radii to the edge of the cornea; dark discolouration of the iris; contraction, irregularity, and immobility of the pupil; effusion of coagulable lymph into the pupil and posterior chamber, occasionally also into the anterior, causing adhesions of the iris to the capsule of the lens, with dimness of sight, sometimes almost amounting to blindness, pain in the eye, and nocturnal pain about the orbit.*

120. This affection was not known until it was ably described by SCHMIDT of Vienna. It may be consecutive of the diseases already noticed; but it often occurs in a primary form, and then generally assumes more or less of the characters of adhesive inflammation, the danger occasioned by it to the organ arising chiefly from this circumstance; for, if neglected or injudiciously treated, the pupil may become completely and irremediably obliterated by effusion of coagulable lymph. Some degree of inflammation of the sclerótica, and of the anterior hemisphere of the crystalline capsule, often extending to the choroid and retina, generally accompanies this disease; but the iris is the focus of morbid action, and the situation of the chief lesions. The primary states of the complaint commence in the pupillary edge of the iris, spread to the rest of the iris, to the capsule of the lens, and, perhaps, to the choroid and retina. The attendant inflammation of the sclerótica may be sympathetic, or otherwise related to it. — *Iritis* has been divided into the *idiopathic*, or that occurring primarily in persons of a healthy constitution; and the *sympathetic*, or that affecting those of an

arthritic diathesis, or supervening in the course of syphilitic cachexia.

121. *Causes.*—*Primary Iritis* occurs most frequently in persons of an unsound constitution—the gouty, rheumatic, and cachectic; and hence it presents certain modifications hereafter to be noticed. It rarely occurs in young and healthy persons; although it may supervene in them, upon the other varieties of ophthalmia. It is excited by the common causes of inflammation of this organ (§ 5.); especially by over exertion, and employment of sight on minute or bright objects; by external injuries or operations on the eye; and by exposure to cold, wet, and atmospheric vicissitudes. These last are the common exciting causes in persons imbued with the syphilitic cachexia, and in those of a rheumatic and gouty diathesis. I do not believe that the use of *mercury* will cause the complaint, if it be given so as to affect the mouth.

122. *A. IDIOPATHIC IRITIS.*—*a. Symptoms and Course.*—Iritis presents various grades of severity, and periods of duration. It may hence be mild or severe; acute, sub-acute, or chronic. I shall adopt Mr. MACKENZIE'S division of iritis into three grades.—*a. In the first degree*, the vascularity of the sclerotic is barely perceptible, and exists only in one or more points, and chiefly behind the upper lid. The ring of the iris next the pupil is slightly discoloured; the pupil is not materially contracted, but is somewhat irregular, without its usual clean and sharp edge, and is hazy; and the motions of the iris are limited and slow. Vision is confused and slightly obscured. There is little or no pain, or aversion from light. This state of iritis may exist for many weeks, and yet be completely removed by suitable treatment.

123. *β.* The *second degree*, or that with evident external inflammation of the eye, is much more frequent than the foregoing. A zone of vascularity is observed in the sclerotic around the cornea, the vessels sinking through the sclerotic, and not advancing into the cornea. The iris, particularly its inner or smaller rings, is discoloured, either from injection of its vessels or the effusion of lymph; and its anterior surface, instead of being smooth and shining, appears dull, puckered, and swollen, especially near the pupillary opening, where it is retracted towards the lens. The pupil is contracted, irregular, motionless, and filled with coagulable lymph, which generally appears like half-boiled white of egg. Epiphora and intolerance of light are considerable, and vision becomes greatly impaired. The pain in the eye is constant, and attended by pain in the orbit and forehead, particularly at night; and by the usual symptoms of inflammatory fever.

124. *γ.* The *third degree* of iritis presents the following characters:—The eye externally is much more inflamed than in the foregoing grades; the redness of the conjunctiva being sometimes so great as to mark for a time the red zone of the sclerotic. Both the smaller and larger rings of the iris are discoloured; the anterior surface being swollen, puckered, and bolstered forwards so as to approach the cornea, excepting its pupillary edge, which is retracted towards the lens. Red vessels and spots of blood are sometimes seen on the iris, but more fre-

quently in the lymph occupying the very contracted pupil. One or more minute elevations, of a yellowish colour, which are in some cases specks of effused lymph, in others small abscesses, appear on the surface of the iris; and pus discharged from these abscesses, with lymph, blood, and serum, sometimes occupy the anterior chamber. The cornea becomes hazy and turbid, and occasionally dotted with minute brownish spots. There are at first great intolerance of light and lachrymation; and subsequently vision is completely, and generally permanently, lost. Flashes of light in the eye are frequently perceived by the patient, indicating the extension of inflammation to the choroid and retina. The pain in the organ is constant, great, and sometimes excruciating; with pain in the orbit and eyebrow, increased at night. When attended with extreme pain, especially in syphilitic cases, very serious changes, even abscess of the anterior chamber, disorganisation of the vitreous humour, &c. frequently supervene. In these, the inflammation is extended more or less to the internal and external tissues of the eye, and general ophthalmitis (§ 153.) is the result.

125. *δ.* The *discolouration of the iris* arises from vascular injection and effusion, and is of a yellowish or greenish tint, in light eyes; or of a reddish hue, in dark eyes: but it is very frequently dull, muddy, and dark; and the natural brilliancy and fibrous arrangement of this part are lost. The *effused lymph* is seen first at the pupillary edge, and afterwards on the lesser circle of the iris; causing a villous, rough, elevated, or irregular surface or outline of the part. The lymph may be in distinct masses of very various sizes on the anterior of the iris, or at its pupillary margin; and, in the most acute cases, it may fill the pupil or anterior chamber, or even the posterior chamber. The *colour* of the effused lymph is sometimes a light yellowish brown or ochrey; but a rusty hue is most common. It is occasionally of a light dirty yellowish tint, particularly when it is abundant, and fills the anterior chamber. In this case, or when a small abscess in the iris is discharged in this situation, a form of hypopyon is the result. The *pupil* is contracted, and becomes more and more so in the progress of the complaint. The effusion of lymph and adhesion render it also angular, irregular, and fixed at one or more points, and free in others. It loses its thin, sharp, and well-defined edge; and becomes dull and cloudy, or otherwise discoloured.

126. *ε.* The *acute states of iritis* are observed in persons of a full habit or robust constitution, after the action of powerful causes, especially if they continue to act, and the case have been neglected at the beginning; and in cachectic conditions of the frame. They are attended by the usual characters of severe vascular action; especially injection of the vessels, extreme contraction of the pupil, effusion of lymph, dulness of the cornea, external redness, loss of sight, violent pain in the eye, and severe headache, with watchfulness, restlessness, and febrile disturbance, terminating, in a few days, in disorganisation of the interior tissues, and in irreparable loss of vision.—*In chronic cases*, the origin of disease is almost imperceptible, and its progress slow. Little or no pain is felt, and the external

redness is very slight or unobserved. At last, lymph is effused, vision is impaired, and the complaint is brought under treatment.—*The sub-acute cases* are intermediate between these two extremes. The chronic form may also follow upon an inactive or partially successful treatment of the acute and sub-acute forms; but it usually presents itself in the *first grade*; the acute most commonly assuming the *third*, and the sub-acute the *second grades*.

127. *b. Consequences and Prognosis.*—*a. Change of texture and colour of the iris* follow inflammation which has been violent or of long duration. General adhesion of the iris to the cornea may occur, and lead to staphyloma; or the iris may become adherent both to the cornea and to the capsule of the lens, occasioning anterior flattening of the eye. This is, however, very rare. Dropsical enlargement of the anterior chamber, with closed pupil and staphyloma sclerotica, may likewise supervene (LAWRENCE).—*β. After acute or sub-acute attacks, the pupillary margin often becomes adherent* to the capsule of the lens, either throughout, or in one or more points. When the inflammation has disappeared, the adhesion still continues, or is reduced to slender threads admitting of partial motion. In some cases, adhesions of the iris are detached, leaving black marks on the capsule, which are permanent.—*γ. An adventitious membrane* may form in the pupil, from organisation of the lymph effused on the surface of the capsule. Its opacity is greatest in the centre; and it may be connected with partial adhesion of the iris. In rarer instances, the adventitious substance is seen in one side of the pupil, and attached to the edge of the iris (*Aresia Iridis incompleta*).—*δ. Closure of the pupil* follows effusion into the posterior chamber, and the formation of an opaque adventitious substance to which the circumference of the pupil is fixed (*Aresia Iridis perfecta*). This adventitious membrane may extend over the anterior capsule, causing adhesion of the uvea to the lens, and enlargement of the anterior chamber.—*ε. Atrophy of the globe* may supervene upon copious effusion into both chambers, and deposition of lymph behind the iris in such quantity as to cause bulging of the sclerotica, or to escape through this membrane and raise the conjunctiva. In this case, the fluid is absorbed after the subsidence of the inflammation; but the internal parts of the ball are so altered that they waste and become flaccid, particularly after complete closure of the pupil. The vitreous humour may also be rendered fluid, and the eye soft, without shrinking in size; but this occurs only after acute syphilitic iritis.—*ζ. Impaired vision* may be the result of the extension of inflammation to the posterior tunics, although the disease has been arrested by appropriate treatment; and may follow the acute, sub-acute, or chronic states of the disease. The impaired vision may be caused solely by the lesions produced in these tunics, or by these and the changes in the pupil conjoined.

128. *c. The Prognosis.*—When the disease is recent, and appropriate treatment is adopted, effusion into the texture, or on the surface, of the iris, will be removed by absorption upon the subsidence of the inflammation. Hence we need not dread the result, if the changes be confined to the iris, although the effusion be copious. But when

the complaint has continued some time, and is attended by increasing contraction of the pupil and effusion of lymph, with organisation of the latter into adhesions and adventitious membranes; or when the consequences described above (§ 127.) are present, or inflammation extends to the posterior parts of the globe and retina, or to the cornea with more or less opacity; the greatest danger to vision is to be apprehended. In most cases, a guarded prognosis should be given; for it is often difficult to determine how far the posterior tunics may be affected. Change of colour in the whole iris, with great contraction of the pupil, and an opaque substance in it; intense external redness, severe and deep-seated pain, extinction of sight, and flashes of light in the eye; large effusion behind the iris, and bulging of the sclerotica; and a protruded state of the iris, and adhesion of the pupil; are all hopeless states of the organ. If unfavourable changes have not appeared, recovery may take place, although the complaint has been of three or four weeks' duration, and sight is much impaired.

129. *d. The Diagnosis of iritis* cannot be difficult, if the history of the case be considered, and the state of the iris carefully examined. The affection most resembling iritis is inflammation of the capsule of the lens. Nebulous, contracted, and fixed pupil, discoloured iris, adhesions between the iris and capsule, are present in the latter, which, however, often supervenes in the course of iritis, and generally attends its most acute attacks; whilst, on the other hand, inflammation of the crystalline capsule is attended by some degree of iritis. The one is thus reciprocally consequent upon the other.—*Retinitis* resembles iritis chiefly in the great contraction of the pupil; but the former is more sudden, its progress more rapid, its attendant headach more violent, and vision more rapidly impaired, than in the latter.

130. *e. Treatment.*—The indications of cure are—1st, to subdue the inflammation; 2d, to prevent or arrest the effusion of lymph; 3d, to promote the absorption of what has been effused; and 4th, to preserve the pupil entire. They are to be accomplished by bloodletting, mercurials, belladonna, &c.—*Bloodletting*, in acute and sub-acute cases; in young, robust, or plethoric persons; when the pain is severe, and febrile disturbance considerable; and the inflammation extending to the internal tunics; must be most promptly and actively practised. It will often be necessary to repeat it; and even to follow it by *cupping* on the nape of the neck, or behind the ears, or on the temples. In the circumstances now stated, local bleeding cannot be confided in alone. But, in chronic, sub-acute, or mild states, cupping will be preferable. *Leeches* may be employed; but they are, unless a great number be applied, much less efficient than cupping. Immediately after the first bleeding, a full dose of *calomel* and *James's powder*, with *opium*, should be given, and repeated at bedtime; and an active cathartic draught (F. 216.) in the morning, aided by a terebinthinate enema (F. 150, 151.). The specific effects of *mercury*, which are most effectual in fulfilling the second and third indications, will be hastened by its combination with an antimonial; and, if the bowels be acted upon daily by a draught containing equal parts of the spirits

of *turpentine* and *castor oil*, or a larger portion of the former, the specific operation of the calomel will not be prevented, or even delayed, but the beneficial effects on the disease will be insured.

131. *Belladonna* is of great benefit in every stage of the complaint, and should be applied as directed above (§ 112.), contemporaneously with the exhibition of mercury. Although the pupil be contracted, and effusion or even adhesion has taken place, the specific operation of the latter, and the effects of the former on the iris, will elongate or even entirely detach the adhesions, if they are soft or unorganised. In addition to these, *diaphoretics*, *diuretics*, and warm pediluvia are beneficial. The bowels ought to be kept freely open by the substances already noticed. *Turpentine* may be used for this purpose, or with the view of aiding the effects of calomel, or even as a substitute for it, as advised by Mr. CARMICHAEL, who prescribes it in drachm doses, three times a day, suspended in almond emulsion. *Blisters* are of doubtful efficacy; Mr. LAWRENCE decides against them.

132. *B. SYMPATHETIC IRITIS.* — *a. Syphilitic Iritis*, or inflammation of the iris occurring in persons tainted by the syphilitic poison, is, perhaps, the most common variety of this disease. It is a symptom of syphilis in its constitutional stage; and, although sometimes appearing alone, it is more frequently one of several secondary symptoms, especially ulcerations of the throat, eruptions, swellings of the periosteum, pains of the limbs, affection of the nose, &c. It occurs most frequently along with the earlier secondary affections, and sometimes appears before the primary disorder is cured (LAWRENCE). It rarely occurs as a symptom of syphilis in infants, although secondary syphilis is not infrequent in them. It may be either *acute* or *chronic*; it is often associated with inflammation of other internal tissues of the organ; and it is most commonly determined or excited by exposure to cold, exertion of the eye, or external injury.

133. *Diagnosis.* — The characters and progress of syphilitic iritis are nearly the same as those of the idiopathic form; yet there are certain points of difference, which are frequently observed in the local symptoms, deserving of notice. These are the tubercular disposition, and the reddish brown discolouration of the lymph effused on the iris; the angular form of the pupil, and its displacement towards the root of the nose; and the violent exacerbations of pain felt chiefly in the brow during the night, and in a slighter degree or not at all in the day. The first and second of these are, however, not constant; the last is always present. But the most certain diagnosis are, the concomitance of other syphilitic affections, and the history of the case. — Lymph is effused from the margin of the pupil in *arthritic iritis*, but not deposited in a distinct form, and the adhesions are generally white; and both in it, and in the idiopathic variety, the pupil commonly retains its circular figure and central position.

134. *b. Arthritic Iritis.* — Inflammation of the iris is frequent in the *gouty diathesis*, but less so in the *rheumatic*, unless as a consequence of rheumatic inflammation of the sclerótica (§ 97.). In the *gouty*, it occurs most commonly in the iris from the commencement, although often some

other tissues of the organ are affected at the same time; but, in the *rheumatic*, it rarely begins in the iris. The *gouty modification* is generally *acute*, and very severe; the *rheumatic, sub-acute*, or *chronic*, and more mild. — The former generally commences with pain of the eye, intolerance of light, lachrymation, and zonal redness of the sclerótica. Pains are felt in the orbit, brow, and forehead. The iris soon becomes dull and discoloured; the pupil contracted, and fixed at one or more points to the capsule of the lens. The reddish zone in the sclerótica is of a dull or nearly livid tint, and does not advance to the edge of the cornea, but leaves a narrow white ring between. After a violent attack, with impaired vision, the symptoms subside, and sight is restored, the iris being attached to the capsule by whitish adhesions. This form of iritis often returns again and again, the eyes recovering almost completely after repeated attacks. Mr. LAWRENCE met with a case in which the disease returned fourteen times; yet vision was not materially impaired, though adhesions in each eye connected the pupillary edge of the iris to the capsule. But frequently a fresh effusion attends on each attack, until the pupil is more and more contracted, and at last filled with opaque adventitious membrane; the texture of the iris, notwithstanding, generally remaining but little altered.

135. *c. Scrofulous Iritis.* — This variety is consecutive of strumous ophthalmia (§ 68.), the inflammation extending from the external tunics. It is commonly preceded and accompanied by changes in the cornea, preventing the lesions of the iris from being observed. Hence it often escapes detection until it has completed its course. It very rarely occurs as a primary affection. Mr. MACKENZIE adduces a case in which the attack seemed primary; but its history is not conclusive on this point.

136. *Treatment.* — *a. The syphilitic variety* requires *local bleedings* and *mercurials*, as advised for the idiopathic disease, and in similar combinations, until the symptoms and the constitutional malady, on which the local one is engrafted, are entirely removed. *Turpentine* may also be employed as an auxiliary, and to open the bowels, either as directed by Mr. CARMICHAEL, or as prescribed by myself (§ 130. 131.). *Opiate frictions* around the eye, and *belladonna*, are also of great service. *General bloodletting* is seldom well borne in this variety, unless in robust or plethoric persons; but full or repeated *cupping* is often necessary.

137. *b. Arthritic Iritis.* — The *rheumatic modification* requires the treatment recommended in rheumatic inflammation of the external tunics — especially *cupping*, *leeching*, *blistering*, *alteratives*, with *colchicum*; and, subsequently, *cinchona* or *quinine*, with full doses of *colchicum*, aided by counter-irritation. *Turpentine* is also beneficial in this variety; but it should be given so as to act moderately on the bowels. Mr. WALLACE advises *bark* to be given from the commencement, when this disease follows low fevers. — The *gouty modification* will be removed by a very similar treatment to that now stated. *Mercurials* given with any other intention than that of removing morbid secretions and excretions, are more injurious than beneficial. *Colchicum*,

in full doses, with the alkaline subcarbonates and warm purgatives, is especially indicated. *Blisters*, and derivatives to the lower extremities; *tepid fomentations* to the organ; frictions with opium and belladonna to the forehead; a free state of the bowels, and attention to diet; are particularly requisite. As the attacks are often repeated, measures of *prevention* should be adopted. The chief of these are, low living, a free state of the bowels and of all the excretions, the removal of plethora, and preserving the organ from cold or over-exertion.—Nothing can be added to what has been stated, both here and in preceding sections (§ 130, 131.), as to the treatment of the *serofulous variety* of iritis.

iii. INFLAMMATION OF THE INTERNAL TUNICS.

SYN.—*Internal Ophthalmia*; *Ophthalmitis interna idiopathica*, BEER; *Ophthalmitis posterior totalis*, ROSAS.

138. DEFIN.—*Severe, deep-seated pain of the eye, with impaired vision, contracted pupil, a sense of aching, tension, and heat, without much external redness, but with symptomatic inflammatory fever.*

139. A. Inflammation may commence in the retina, or in the choroid; but it cannot remain long confined to either. It frequently extends from the iris to the latter, and to other internal parts. The disease probably begins most frequently in the retina, and may, therefore, be designated *retinitis* in its early stage. We are necessarily less acquainted with the phenomena attending it, than with those accompanying iritis. ROSAS considers that the whole retina is not equally affected, but chiefly the vicinity of the yellow spot.—The *Causes of retinitis* are sudden exposure to light; the action of a strong light, as looking at the sun or bright objects; the light and heat of a bright fire; exertion of the eyes, particularly when the rays of light are refracted; and the predisposing and exciting causes described above (§ 4—6.).

140. a. *Symptoms and Course of retinitis.*—The patient complains of pain and aching deep in the eye; of a sense of tension or of heat, aggravated by using the organ, by exposure to light, or by whatever determines the circulation to the head. The pain is often pulsating, and usually extends to the brow and head. The pupil is much contracted; vision is impaired, and hourly becomes more so. In severe cases, the pupil is nearly closed, and sight almost or altogether lost; and flashes or sparks of light are perceived in the eye. At this period there is little external redness, excepting in the sclerotic around the cornea; but there are thirst, white tongue, and fever. With the continuance of the disease, the sclerotic redness increases, and a bright zone is formed around the cornea; and the inflammation spreads inwards to the vitreous humour and to the capsule of the lens, and outwards to the choroid and iris. This last now loses its natural colour, becoming greenish and reddish; and it is pushed towards the cornea. Sight is lost, even before total closure of the pupil takes place. The disease now may be designated *Inflammation of the internal tunics generally*, or the *second stage* of retinitis. The redness of the sclerotic extends; the conjunctiva becomes injected; the pupil often obliterated from effusion of lymph; the cornea somewhat dull; and general ophthalmia

supervenes. The pain of the eye is unequal, or pulsative; is attended by a sense of weight, sometimes of cold; and chills or rigors are felt. Suppuration now occurs, and matter is effused in front of the iris, particularly if the pupil is not entirely closed, constituting hypopyon; and blood is sometimes mixed with it.—Such is the course of the most acute and severe cases of internal ophthalmia commencing in the retina, when uncontrolled by treatment; and the *results* are—1st, Insensibility of the retina, from change of structure—*Amaurosis*;—2d, Contraction and partial obstruction of the pupil, with impaired function of the retina, and opaque capsule and lens;—3d, Closed pupil, with the formation of an adventitious membrane;—4th, Suppuration making its way externally, and leading to destruction of the eye, and collapse of the coats.

141. b. *Chronic Retinitis.*—A very much milder and more prolonged form of retinitis than the foregoing, is often observed in persons who greatly exert their eyes. It is characterised by sensibility to light; more or less weakness or obscurity of vision, especially beyond the distance at which the eye has usually been occupied; with gradual contraction of the pupil, immobility of the iris, and aching in the eyes and forehead. This slight grade of the disease is manifestly confined to the retina. There is but little increase of vascularity externally; excepting, in some cases, a narrow or partial zone in the sclerotic around the cornea. The complaint is aggravated by stimulants and a heating regimen; and benefited by opposite means. It often continues months, or even years, with occasional exacerbations; and either in great measure disappears; or becomes greatly aggravated, or assumes the above severe form.

142. c. The *Prognosis in retinitis* is favourable in the commencement, before the pupil is very much contracted, or vision greatly impaired; but it becomes less and less so in proportion to the duration of the complaint. If misunderstood at the commencement, neglected, or ill-treated, the organ is frequently endangered. If the pupil be much contracted, and sight lost; or if sight be quite gone before the closure of the pupil; blindness will be the result.—If the disease have gone on to general ophthalmia, all that can be hoped is to preserve the form of the eye.

143. d. *Treatment.*—Copious general and local *bleeding*, the active exhibition of *mercurials* until the mouth is affected, the employment of *belladonna*, *cathartics*, low diet, and the rest of the antiphlogistic regimen, as directed for iritis, with complete rest of the eyes and of the body, and exclusion of light, are the most efficacious means of cure. Bloodletting, although early practised, will often fail, if *mercury* be not freely administered. *Turpentine* may be also given to aid its operation, and act upon the bowels. These measures will succeed only in the first stage, before the pupil is closed and sight is lost. Yet, if suppuration have not occurred, it is still requisite, in order to preserve the form of the eye. In the *slight and chronic form*, local depletion, active purging, low diet, attention to the digestive functions, and repose of the organ, are the chief remedies. Open *blisters* behind the ears, or the *ointment of the potassio-tartrate of antimony*, are also beneficial.

144. B. *Choroiditis*—a. *Inflammation of the cho-*

roid, of the hyaloid membrane, of the capsule, &c.,) under the terms *Choroiditis*, *Hyaloiditis*, *Capsulitis*, and *Lentitis*—have been described by JUENGEN, ROSAS, and MACKENZIE. But admitting, from analogy, that inflammation may commence in, and be more or less confined to, either of these tissues, for a longer or shorter time, I question the possibility of their being often distinguished from *retinitis*, with which they must necessarily be in some degree associated. I must refer the reader to the observations of Mr. MACKENZIE on *Choroiditis*. He believes that the choroid, although generally affected consecutively upon iritis, is sometimes *primarily* and separately inflamed. The inference is most probably correct; yet experience shows that such a state of disease can but rarely be recognised. He states that *choroiditis*, in its earliest stages, exists without any signs of disease of the iris, and without any effects upon the sclerótica and retina beyond those which must necessarily arise from the pressure of an inflamed and swollen membrane. The dark colour of the choroid shows through the sclerótica, which thus appears bluish or purplish, and distended. The part most discoloured protrudes, generally, on one side of the ball, and near the cornea; and is of a deep blue tint, with varicose vessels running over it (*Sclerotic Staphyloma*). Several such tumours may surround the cornea, or may protrude on the posterior hemisphere of the organ. A watery fluid is sometimes effused between the choroid and the retina during its progress; and redness is observed in parts of the sclerótica. Although the iris is not inflamed, it is always narrowed or drawn towards the portion of the choroid chiefly affected, causing displacement of the pupil. There are generally attendant intolerance of light, pain, hemimeria, frequently partial opacity of the cornea, dimness of sight, proceeding to total blindness, and febrile disturbance, disorder of the digestive organs. The disease is most common in the scrofulous diathesis; in those who over-use their eyes, without taking sufficient exercise, and who expose them to too much heat and light.

145. *b. The Treatment* consists of copious blood-letting, active cathartics, mercury aided by turpentine, and counter-irritation, in the earlier stages; and, subsequently, the internal use of the preparations of iodine, or the precipitated carbonate of iron; or the iodide of iron, and the sulphate of quinine.

146. *C. Arthritic Inflammation of the Internal Tunics — Ophthalmitis Arthritica*, BENEDICT and ROSAS. — *a.* Arthritic iritis frequently is confined to the iris; but in gouty persons of very impaired constitution, inflammation is either extended to, or almost simultaneously appears in, the retina, the choroid, the lens and its capsule, and the vitreous humour; the sclerótica and cornea being secondarily affected. It usually attacks elderly persons, of a full habit, with bloated, red, purple, and veined faces; and it generally terminates in loss of sight, with dilated pupil and opaque lens or glaucoma. At first the patient complains of increased sensibility to light; of lachrymation; and of a severe burning or tearing pain deep in the globe, with a sensation as if the eye were too large for the orbit. A dull and livid redness is observed in the sclerótica; it increases towards the cornea, but is separated from this part by a narrow white ring. The conjunc-

tiva afterwards becomes injected, and the cornea dull. The pain is now distracting, and extends to the orbit, face, and side of the head: the iris is dark, assumes a dirty appearance, is irregularly contracted and fixed, the pupil often having an oblong or oval figure, in the transverse direction. A greenish discolouration is observed deep in the eye, from lost transparency of the vitreous humour. The posterior tissues swell and push the lens forwards, wedging it into the dilated pupil, and squeezing it even against the cornea. The lens also turns green, yellowish green (*Glaucomatous Cataract*), or dull white. The congestion and swelling of the internal coats distend the sclerótica, or bulge it out in parts; the cornea becomes hazy; and the changes in the iris, pupil, and external tissues, impart to the organ a dead appearance. Luminous flashes are frequently perceived in the eye; but sight is either much impaired or altogether lost — sometimes suddenly — from the commencement. At this stage the symptoms frequently subside, the iris preserving its dull hue, the pupil being fixed and dilated, and sight totally lost. A varicose state of the vessels in the sclerótica sometimes remains; or a dull leaden appearance, with small projections or larger bulgings around the cornea, as in *choroiditis* (§ 144.).

147. This disease generally affects both eyes, either in succession or at once. Its duration is various as well as its severity; and it often assumes a less violent form than that now described, especially when its early symptoms have been mitigated by treatment. In this case, sight is more gradually and slowly extinguished; the pain is less; and the external changes, particularly the bulgings of the sclerótica, are either less, or but slight. It is difficult to determine what tissue is primarily affected; but most probably the choroid, retina, and iris, are almost coëtaneously attacked. The early loss of sight indicates an early affection of the retina; and the equally early tension and pain show that congestion and swelling of the choroid is present from the first.

148. *b. The Prognosis* is extremely unfavourable. If the characteristic symptoms of this affection be present, and more especially if vision be lost, permanent extinction of sight will be the consequence.

149. *c. Treatment* has hitherto been found to have little influence on this disease. Nevertheless, bloodletting; warm purgatives, with full doses of colchicum and alkaline carbonates; revulsants to the lower extremities, or behind the ears, or to the nape of the neck; active doses of turpentine both by the mouth and in enemata, so as to act efficiently upon the bowels and vascular system; subsequently PLUMMER'S pill and the decoction of guaiacum, with the compound tincture of colchicum and liquor potassæ; and full doses of sulphate of quinine, or of cinchona with or without colchicum, &c.; should be fully tried.

150. *D. Inflammation of the internal tissues after fever* sometimes occurs. It has been described by Dr. WALLACE and Dr. JACON. Of forty cases which the former observed, there were only four who had the disease in the left eye, and only two who had it in both. It may occur very soon, or not for some months, after fever; and it presents *two stages*; in the *first* of which, ama-

rotic symptoms are alone present; in the *second* those of inflammation are superadded. The period at which the former commences after fever, and its duration before redness comes on, are very uncertain. In some cases, dimness of sight and *musca volitantes* have been present from the earliest period of convalescence, yet the inflammatory stage has not supervened for weeks or months; and in other instances, the amaurotic symptoms have not appeared till months after the fever, and have been soon followed by the second stage. The inflammatory changes disappear before the amaurotic symptoms (WALLACE).

151. Dr. JACOB met with seventy or eighty cases of the disease in one year. It is most frequent among the poor, in young persons and in females; and attacks always only one eye. The affection of the retina having been present from a few days to several weeks, the transparent parts of the eye become more or less clouded or opaque; the circumference of the cornea presents an opaque whitish appearance or circle, resembling the arcus senilis. The anterior chamber seems clouded. The iris is always dull, and altered in colour; but tubercles of lymph or abscesses are not seen in it; and it often moves actively. The pupil is slightly irregular; yet it does not contract adhesions, or become closed. Ilypopyon sometimes ensues. In the worst cases, the lens becomes partially opaque, and presents an opaline amber colour. When vision is permanently lost, it is generally owing to this change. Impairment or loss of vision is the earliest symptom; and there generally are intolerance of light, lachrymation, and a stinging or darting pain through the eye to the temple or nose. Sometimes the suffering is slight; but it is usually increased on exposure to strong light (JACOB).

152. *The Treatment* recommended by these two experienced writers is diametrically opposite. Dr. WALLACE found depletion and mercury insufficient for a cure; he therefore gave half a drachm, or a drachm, of bark in powder, three or four times a day; or the sulphate of quinine in two grain doses. Dr. REID also employed bark with success in this sequela of fever. Dr. JACOB, however, states, that bleeding locally or generally, purgatives and antimonials, blisters and opiate stupes, and mercurials with opium and belladonna, are the most efficacious means of cure. He adds, that the relief from mercury is so certain, that he has trusted to it almost exclusively, with the assistance of belladonna. He has generally found two grains of calomel, with a quarter of a grain of opium, or five grains of blue pill alone, three times a day, answer every purpose; tenderness of the gums coming on in eight or ten days. If the pain be severe, he combines hyoscyamus or belladonna with the dose taken at bedtime. He tried the sulphate of quinine in four cases for eight days; but finding no relief, he gave mercury, which effected a cure. The cases occurring after typhus fever, recorded by Mr. HEWSON, and which were similar to those described by Drs. WALLACE, REID, and JACOB, readily yielded to mercurial treatment.

IV. INFLAMMATION OF THE WHOLE EYE. SYN.—*Ophthalmitis Idiopathica*, BEER; *Ophthalmitis Universalis*, WELLER; *Inflammation of*

the Globe, LAWRENCE; *Phlegmonoid Inflammation of the whole Ball*.

153. CHARACT.—*Severe deep-seated pain; increased internal redness and tumefaction; a sense of tension, and a feeling of the organ being too large for the orbit, and about to burst from it; early loss of sight, with discoloured iris, and contracted, immoveable pupil; swelling and immobility of the globe, with partial protrusion of it and the eyelids; and severe inflammatory fever.*

154. A. This severe disease has been well described by Mr. LAWRENCE. It consists of inflammation of the internal and external tissues, and is not of common occurrence. It is met with chiefly in very robust constitutions, and persons of a phlogistic diathesis and full habit of body. It is most frequent in the right eye, as is the case with ophthalmic inflammation generally. Mr. LAWRENCE states, that of 134 cases of ophthalmia commencing in one eye, 95 began in the right. General ophthalmitis is most commonly caused by severe injuries of the organ; by the explosion of gunpowder before the eye; by great heat and light striking upon it; and fragments of stone, iron, &c. propelled against it.

155. a. *Symptoms and Course.*—At the commencement, the characteristic injection of both the sclerótica and conjunctiva is evident; with a severe burning or throbbing pain, and a sense of bursting distension. The surface of the organ is stiff and dry; but copious lachrymation soon comes on, and is increased by exposure to light. The external redness increases; and the conjunctiva swells into a broad firm ring of chemosis around the cornea, which it partially overlaps. There are intolerance of light, dimness of vision, contracted pupil, impaired brilliancy of the iris, and acute sympathetic fever. This constitutes the *first stage* of the disease.—The motions of the globe and lids now become difficult and painful; and the pain more and more violent, extending to the brow, cheek, temple, and head. The previously blue or grey iris assumes a dull greenish hue; and the brown or black, a reddish tint. The eyeball swells and loses its power of motion; the cornea grows muddy, and, by degrees, opaque; but vision is generally lost before these changes supervene. The patient perceives luminous flashes or sparks in his eye, owing to disordered action in the retina; and the vascular distension of the internal tissues generally occasions a sense of bursting. The deep-seated swelling and external chemosis partially evert the inflamed eyelids, which thus resemble, especially the inferior, a red fleshy mass; and both the ball and lids are protruded, and immoveable. The *second stage* is now fully developed.—Sympathetic inflammatory fever always accompanies this severe disease. The local symptoms are preceded, or attended at their commencement by chills or rigors, followed by headach, white tongue, thirst, hot and dry skin; and accelerated, hard, and full pulse. These are increased at night, and accompanied with watchfulness, and throbbing in the temple and eye.

156. b. *The Consequences*, or the *second stage*, according to WELLER, are supuration and opacity of the cornea, &c. If the disease be not arrested, the pain becomes throbbing; delirium sometimes occurs at night; and chills or rigors

are felt, indicating impending suppuration. The cornea is first a dull white, and then yellow, and matter is formed. The throbbing and bursting pain continues, notwithstanding, for some days, until the cornea bursts externally, and gives exit to the matter; the coats of the eye collapsing, and the form of the organ being lost. When the progress of the disease has been checked by treatment, the cornea remains opaque, and the pupil is either closed or very much contracted, and the aperture filled by adventitious membrane; vision being either much impaired or entirely lost. Even when recovery takes place, with an open pupil and clear cornea, the retina has generally suffered so much as to cause some imperfection of vision (LAWRENCE).

157. c. *Diagnosis*.—This complaint is characterised by the simultaneous affection of both the internal and external tunics; and is distinguished from the *sympathetic* or *specific* inflammation above considered, by the following circumstances:—(a) Redness, pain, swelling, intolerance of light, lachrymal discharge, and impaired vision, are all equally and co-ordinately developed; but in the specific inflammations, one or other of these is always predominant over the rest, and accompanied by some peculiar local and constitutional affection.—(b) These symptoms commence at the same time in an equal degree, and continue very nearly so throughout; but in the other ophthalmiæ, this correspondence is remarked neither at their commencement, nor during their progress.—(c) The course of the malady is regular and continued, and it always terminates in suppuration of the globe, if not arrested by treatment; whilst the others remit more or less, and only occasionally terminate in this manner.—(d) Phlegmonoid ophthalmitis is always attended by severe sympathetic fever; but the specific forms are generally without fever, even when most severe.

158. d. *Treatment*.—It is only in the *first stage* that we can expect to preserve the sight. In the *second stage*, this will rarely be accomplished. When vision is altogether lost in this period, the preservation of the form of the organ can only be hoped for. If symptoms of suppuration have appeared, the eye will be destroyed. In the first and second stages the most active antiphlogistic measures, as directed in internal ophthalmia (§ 143.), must be practised: general bloodletting, cupping, leeches applied around the eye, and scarification of the protruded lids; with active cathartics; calomel and James's powder in full and repeated doses; turpentine given by the mouth, and in enemata with castor oil; and belladonna; constitute the chief remedies. If suppuration have occurred, the anterior chamber being full of matter, the evacuation of it by a free opening into the cornea, will give relief, and not increase the inevitable mischief.

159. B. *General Ophthalmitis consequent upon the absorption of purulent or morbid matters into the circulation*, may occur. It has been noticed chiefly after phlebitis, by Mr. ARNOTT and Mr. HIGGINSBOTTOM; and is most frequent in the puerperal state, as a consequence of uterine phlebitis. The local symptoms in the early stages are the same as in the idiopathic, but less violent, and more insidious and rapid, and always terminating in suppuration and sloughing of the cornea.

The constitutional symptoms are very different, and are of a typhoid and adynamic type. All the cases that have hitherto been recorded, have terminated fatally.

160. C. *An Intermittent form of Ophthalmia* has been described by some writers, particularly HOFFMANN, CURRY (*Trans. of Med. and Chirurg. Soc.* vol. iii. p. 348.), and HEUTER (*Lancet*, No. 331. p. 473.); but I agree with Mr. LAWRENCE, in considering a truly intermitting form of inflammation of any of the tissues of this organ as not to have been made out. Exacerbations, relapses, or returns, of the disease, from persistence or recurrence of the causes, may have been mistaken for an intermittent form. Frequently recurring attacks of inflammation in some one or more of the tissues of the eye, especially of the conjunctiva, and in slight and chronic forms, are sometimes caused by the sympathetic irritation of inflamed or carious teeth.—Of this form of disease, which is not noticed by writers, I have seen two or three instances; and the removal of the adjoining irritation curing that depending upon it.

161. I should now have proceeded to consider the *consecutive and malignant alterations of the tissues of the eye*; but these, in a practical point of view, fall mostly within the province of the surgeon, a strictly medical treatment having but little influence in removing them. The malignant diseases of this organ are the same as those observed in other viscera, and are considered under distinct and appropriate heads. The functional disorders are treated of in the articles AMAUROSIS, PALSY, and SIGHT.

FAINTING. SYN. — *Αισθηψυχια*, Hippocrates. *Αποψυχια*, Galen. *Syncope* (from *συνκοπτω*, conculo); *Deliquium Animi*; *Defectio Animi*, Celsus. *Defaillance*, Fr. *Die Ohnmacht*, Germ. *Swimming*.

CLASSIF. — 2. Class, 2. Order (Cullen).
4. Class, 4. Order (M. Good). I. CLASS, III. ORDER (Author).

1. DEFIN. — *Temporary depression of the animal and vital actions, with pallor, cold perspiration, remarkably weak pulse, or absence of pulse at the wrist; respiration and sensation also being nearly abolished for a short time.*

2. The terms used by HIPPOCRATES and GALLEN are synonymous with *Syncope*, a word of modern use. *Leipthymia* has been considered by later writers, particularly MORGAGNI, DR. GOOD,

and Dr. ASH, either as the same as syncope, or as signifying a lesser grade of this affection. The definition which SAUVAGES has given, of *leipothymia*, assigns it a specific difference from syncope, or the usual form of swooning or fainting. He states it to be — “Subitanea et brevis virium dejectio, superstite pulsus vigore, et cognoscendi facultate.” I have had several opportunities of observing attentively the whole progress of this affection; and I admit the accuracy of this definition, with the exception of the continuance of consciousness, which is generally somewhat impaired, although not altogether lost. The pulse is unaltered from the state in which it was before or after the seizure, or not materially influenced; and in some cases I have found it so strong as to prescribe depletion; but the respiratory actions are nearly abolished. *Leipothymia* is, therefore, an affection of the animal and respiratory functions, that of the heart not being impaired. The slight or imperfect seizures often observed to precede fully developed *epilepsy*, or to occur between, or usher in, the severe attacks, and described in that article (§ 41. 52.), are examples of the *leipothymia* of SAUVAGES.

3. *Fainting* and *Swooning* are grades of the same affection, the latter being a more complete and prolonged state of the former. *Fainting* may occur after very short or irregular periods — the *Syncope recurrens* of GOOD. It is then often followed by palpitations of the heart. — *Swooning* is much less prone to recur, but is sometimes followed by severe reaction. SAUVAGES has divided syncope into as many varieties as there are principal causes inducing it. — Dr. GOOD has adopted a somewhat similar division. As, however, it varies chiefly in degree, from whatever cause it proceeds, no further distinction, than that which I have just made, need be assigned to it.

4. I. DESCRIPTION, &c. — Fainting is commonly preceded by languor, a sense of sinking at the epigastrium, anxiety, confusion of intellects, obscuration of vision, cold partial sweats, giddiness and ringing in the ears, pallid countenance and quivering of the lips, and coldness of the extremities. These may continue for some time, constituting what is usually called faintness, and disappear; or they pass into full fainting or swooning more or less rapidly. It is seldom that fainting occurs without these precursors; but when it is fully developed, respiration almost ceases, and consciousness is nearly or altogether lost. The action of the heart, however, still continues, but feebly; and, although the pulse disappears from the wrist, as in full swooning, it may still be felt in the carotids; or the heart will be heard to beat on auscultation. In some instances, relaxation of the sphincters, and discharge of the excretions, are said to have occurred. But this is rare in swooning, although it sometimes supervenes in *leipothymia*, in which the brain is rather oppressed with blood, than deprived of it; and in which the pulse retains its vigour. Sickness, or even vomiting, sometimes follows faintness, or accompanies recovery from fainting.

5. The sensations ushering in syncope are generally more or less distressing to the patient, and are sometimes described as accompanied by a feeling of death. MONTAIGNE (*Essais*, liv. ii. cap. vi.) found them rather pleasurable than

otherwise; and therefore infers, that those attending upon dissolution must be similar. CHAMBERET experienced the like feelings. The *duration* of the seizure varies from a few seconds to one or two hours; but commonly from half a minute to ten or fifteen. It has extended in some instances to several hours. Much longer periods have been mentioned by writers; but their actual occurrence is questionable.

6. *The Consequences or Terminations* of syncope are — 1st, A return of the functions, respiration becoming more sensible and often suspirious, and eructations or vomiting occasionally supervening; — 2d, Palpitations of the heart, or general vascular reaction; — 3d, Hysterical symptoms, or a fully formed hysterical paroxysm; — 4th, Convulsions, general or partial, with or without consciousness; but they are much more frequently consequent upon *leipothymia* than upon true syncope; — 5th, Partial, or slight paralysis, or prolonged vertigo; — 6th, In cases connected with passive enlargement of the cavities of the heart, and attended by a very slow as well as a very weak pulse, coagulation of the fibrinous portion of the blood has taken place in these cavities, and after some time occasioned death; — 7th, Dissolution has occurred in extreme cases, owing either to the complete depression of cerebral and nervous power, and the consequent inaction of the heart; or to the asthenia and wasting of the parietes of this organ, in conjunction with nervous depression. The fifth and sixth of these are rare; instances, however, of the latter, are adduced in the article HEART. The termination in dissolution is not so rare; and is chiefly observed in cases of great debility or exhaustion from extreme or protracted pain, or from parturition; and particularly when a sitting or erect posture has been suddenly assumed or too long retained in adynamic fevers, and after exhausting discharges or depletions. Some years since I saw swooning caused by strangulated femoral hernia, that passed into complete tetanus of many hours' duration.

7. II. CAUSES. — The causes of syncope are strictly *occasional*. I shall consider them with reference to their operation. — a. *The causes which act more immediately on the nervous system*, are chiefly various impressions made upon the organs of sense, and depressing moral emotions. The odour of various flowers, according to the idiosyncrasy, sometimes occasions it. FABRICIUS HILDANUS has seen it by the smell of vinegar; and MARCELLUS DONATUS, by soft music. The airs of their native land have induced it in persons subject to nostalgia. Various unpleasant sights, or objects of aversion, have caused it — as the sight of blood, of surgical operations, or of a corpse; also sudden terror, fear, anxiety, disappointment. The impression made by mephitic or infectious emanations upon the nerves of smell, frequently induce more or less of faintness. Concussions and injuries of the brain; blows upon the epigastrium; shocks of the whole frame; gyration; rotatory motions, and swinging; excessive or prolonged pain; pleasurable sensations carried to excess, particularly the sexual orgasm; the exhaustion consequent upon inordinate excitement, long fasting, and the abstraction of accustomed stimuli; likewise operate principally in this way.

8. *b.* The causes which affect chiefly the vascular system, are the advanced stages of diseases of the heart and pericardium, particularly passive dilatation of the cavities, or softening of their parietes. In cases of this kind, a fatal termination often supervenes in the form of syncope, as remarked by BONET, LANCISI, SENAC, MORGAGNI, MECKEL, and others. The most common of this class of causes is the loss of blood, particularly from arteries whilst in a standing or sitting posture. HOFFMANN met with an instance of syncope from bloodletting proving fatal, and numerous similar cases are on record. During the period preceding the stage of excitement in fevers, syncope may follow the loss of an ounce or two of blood; and yet the same patient may bear, a few hours afterwards, when reaction has become developed, the loss of two or three pounds without this effect being produced. Excessive discharges and evacuations occasion it, by diminishing the circulating current, by deriving from the brain, and by exhausting nervous and vital power. Various circumstances retarding or preventing the return of blood to the right side of the heart, will sometimes cause fainting. The sudden removal of prolonged pressure, as of dropsical effusions and of the contents of the uterus in parturition, often occasions it; but whether the removal of pressure acts in this latter manner or not, or in favouring a sudden and overpowering reflux of blood to the heart, is difficult to determine. Something may also be owing to the consequent diminution of resistance to the heart's action, and change in the accustomed states of several viscera, and to the effects upon the abdominal ganglia. It is very doubtful, that the syncope, which sometimes occurs upon the removal of the ligature from the arm after bleeding, and upon stopping the evacuation, arises altogether from the loss of blood, as fainting often takes place in such circumstances, although no indications of its approach existed at the time when the flow was stopped. In this case at least, if not in others where pressure is removed from internal venous trunks, the suddenly increased return of blood overloads the right side of the heart, and overpowers its action for a time, until the load is removed either slowly or more rapidly by restoring nervous energy. In this manner general or relative plethora may cause syncope, the moving power being insufficient for the body to be moved.

9. *c.* There are certain causes of swooning which seem to act both upon the nervous system and upon the heart, or upon the latter through the medium of the organic system of nerves. — These are—1st. Agents from without that make their impression on the respiratory passages. Some of the first class of causes act also in this way; especially mephitic or infectious effluvia. Instances have occurred of persons having swooned upon exposure to the effluvia of pestilential diseases, and of death having soon afterwards taken place. Such an occurrence could not have arisen from the effect produced upon the brain solely, or even chiefly. Indeed, I believe that all agents which impress nerves of sensation, especially those of smell and taste, act more immediately and energetically upon the heart than is usually admitted. — 2d. Sudden and intense changes induced in various parts of the body may be sympathetically

propagated to the brain and heart, or may coëtaneously affect them; as when syncope follows gangrene, or the passage of noxious matters into the circulation, or the ingestion of sedative or noxious matters, or supervenes upon affections of the stomach, or occurs after the invasion of fever, and before reaction comes on. In these cases, however, congestion of the large vessels and right side of the heart, owing to, and associated with, depressed power of the organic nervous system, is chiefly concerned in overpowering or weakening the heart's action, and lessening the supply of blood to the brain. — The increased function of remote organs, and the derivation of vital action from the brain or heart, or from both, as in impregnation and quickening in the female, and in various diseases of the abdominal organs, will sometimes induce fainting. The sudden transition from a recumbent to a sitting or an erect posture, in delicate or debilitated persons, is often followed by vertigo, quickly passing into swooning; and is obviously caused by the rapid return of blood from the head, and the diminished supply to this part, in conjunction with its sudden and overpowering reflux to the left side of the heart.

10. It is unnecessary to adduce every circumstance that occasionally causes fainting, as they may be referred to the above heads; and as there is scarcely an occurrence or external agent which will not, on some occasion or other, however rare, induce it, when acting energetically on susceptible constitutions. On many, however, of the occasions in which it has been said to occur by writers, leipthymia has been mistaken for, and confounded with, it. Thus HEBERDEN, in stating that epileptics are liable to faint upon waking in the morning, has mistaken this state for leipthymia, which is common in the horizontal posture, sensation and respiration being nearly abolished, but the pulse retaining its fullness and strength; whereas syncope rarely comes on, and generally disappears in this posture. In epileptic patients, leipthymia often occurs both when falling asleep and on waking; but syncope principally on suddenly assuming the erect posture.

11. There are some occasional causes, the operation of which is not easily explained, such as warm baths, heated rooms, and overcrowded assemblies; sitting with the back to the fire, particularly at a meal; and great rarefaction of the atmosphere. These, probably, act chiefly on persons whose circulating fluid is deficient in quantity, by deriving it from the heart and brain. They more frequently, however, occasion leipthymia and apoplexy or convulsions, especially in the plethoric.

12. The occasional exciting causes seldom act excepting on susceptible or predisposed constitutions. These are—the debilitated by scanty nourishment, by acute diseases and profuse discharges; persons whose circulating fluid is deficient in quantity; the delicately constituted, especially females; and peculiar idiosyncrasies. Those who possess much sensibility and little moral courage or force of character—who have been effeminately brought up, indulged in childhood and youth, and unaccustomed to the contrarieties of life—are very subject to syncope. Some females, especially the hysterical, weak

and excessively indulged, are remarkably liable to faint from the slightest mental or corporeal cause; and there is reason to believe that the liability is increased by repetition or the habit of fainting.

13. *Pathological Inferences.* — 1. In syncope, the heart's action never, perhaps, entirely ceases until it terminates in death. — 2. In fainting from hæmorrhage, cerebral influence, especially the voluntary powers and volition, is abolished before the heart's action is reduced to its lowest state; but, unless the swoon be complete, sensibility and consciousness are not entirely suspended. — 3. The like obtains in fainting from moral emotions and impressions made upon the senses; cerebral influence is first diminished, and instantly afterwards the action of the heart is weakened, the weakened vascular action still further impairing cerebral power, until fainting is the result. — 4. Several causes, both external and internal, or pathological, particularly those already specified (§ 9.), seem to act coëtaneously and co-ordinately upon the brain and heart, through the medium of the organic system of nerves; whilst others of the same class of causes (§ 9.) seem to influence more immediately and especially the heart through the same channel. — 5. Certain causes may suddenly derive the circulating fluid to the external surface or other parts; and the sudden diminution of the quantity returned to the heart and propelled to the brain, may induce faintness or full syncope. — 6. The sudden reflux of blood to the right side of the heart, especially when it supervenes rapidly upon the states just specified, may occasion fainting, by overpowering the heart's action, and thereby diminishing the supply of blood to the brain. — 7. Fainting may arise from inflammation of the heart, or effusion into the pericardium. — 8. It may also occur from the imperfect action of the heart caused by deficient organic nervous power, particularly of the cardiac nerves, with or without dilatation of the cavities, and weakness or softness of the parietes of the organ. — 9. It may be occasioned by circumstances preventing the return of blood to the heart. — To either of these two last are to be imputed the fatal cases of syncope related by Mr. CHEVALIER and Mr. WORTHINGTON, in which the cavities of the heart were found empty and relaxed, and the large veins adjoining devoid of blood.

14. Indeed, *death* may supervene in any of the modes in which syncope is produced, especially when carried to the extreme. Thus I have seen, in two instances, a moderate dose of the acetate of morphine occasion loss of voluntary motion, and scarcely perceptible pulse and respiration — the characteristic phenomena of swooning. A larger quantity might have caused death; its operation — extended from the stomach to the heart and brain — being the same, but so great as to put an end to the functions of these parts. Other causes, inducing any one of the pathological states now assigned, may act, in favourable circumstances, and in highly predisposed persons, so energetically, as to terminate altogether the vital actions; predisposition or pre-existent states of the frame, such as have been mentioned, being often as influential in producing the result, as the more direct cause.

15. III. DIAGNOSIS. — Syncope may be con-

founded with *apoplexy*, with the seizures to which the term *leipothymia* is strictly applicable, with *asphyxy*, with certain states of *hysteria*, and with *death*. — (a) The strong, laboured, or stertorous breathing, and the full strong pulse; sufficiently distinguish *apoplexy* (see that article, § 66.) from fainting. — b. In *leipothymia*, volition and voluntary motion are abolished, and consciousness nearly or altogether: but the pulse either is not affected, or is even fuller than usual; and it is more frequently the first stage of, or followed by, epileptic and apoplectic seizures, than true syncope. Frequently, also, *leipothymia* is intimately associated with epilepsy, the former being either the earlier manifestations or the lesser grade of the latter. — c. In *asphyxy*, the actions and functions of respiration are the first to cease; the circulation of venous blood continuing for some time, until, owing to the privation of pure atmospheric air, the passage of blood through the lungs becomes obstructed, as first shown by Dr. WILLIAMS (*Edin. Med. and Surg. Journ.* Oct. 1823.), when total arrest of the pulmonary circulation, abolition of the cerebral and nervous functions, and lastly, *cessation* of the heart's action (see ASPHYXY, § 14 *et seq.*), are the consequences. Respiration and circulation are here quite at an end; and the countenance and general surface are reddish, livid, tumid, or bloated; whereas in *syncope* the face and surface are pale and collapsed, and the respiratory functions and circulation still continue, although in a low and occasionally almost imperceptible state. In the former, there is remarkable congestion of the lungs and head: in the latter, the brain is generally insufficiently supplied with blood; and the circulation of the lungs, although languid, is seldom obstructed, and never altogether arrested, unless a termination in death supervenes. — d. Various manifestations of *hysteria* either very closely resemble fainting, or are in some way or other associated with it. The more remarkable phenomena of *hysteria* may follow, or precede, fainting, most frequently the former; but the loss of motion and sensation often partakes more of the characters of *leipothymia*, than of swooning, the pulse at the wrist being but little affected. Pain under the left breast, borborygmi, and a sense of suffocation, which commonly precede the hysterical form of syncope, sufficiently mark its nature; and even when these are not present, other signs soon manifest themselves, especially convulsions, weeping, laughing, &c. (See HYSTERIA.) — e. Syncope is rarely so profound as to be mistaken for death; but PORTAL and CHAMBERT, with some writers on medical jurisprudence, concur in thinking that it may be both so complete and prolonged as to endanger premature interment in countries where the last rite is early performed. Whether or not the action of the heart, which cannot be altogether abolished even in such cases, may be detected by the stethoscope, I am unable to state; but it surely cannot continue many minutes without detection upon a strict scrutiny, unless death have taken place. The state of the cornea, which is soon covered with a film, or deprived of its delicate transparency, and afterwards collapsed; the appearances of the thorax upon examination; the signs yielded by auscultation; the condition of the body in respect of flexibility, &c.; and the

temperature under the armpits, &c.; will generally decide the question even in the most doubtful cases. Placing a mirror before the face, or down beneath the nostrils, and observing whether the former be moistened, or the latter moved, have been long popular means of ascertaining the certainty of death, as happily shown by SHAKESPEARE (*Lea*, act v. sc. 3., and *Henry the Fourth*, act iv. sc. 3.)

16. IV. TREATMENT.—Syncope is frequently not only its own cure, but often the means of removing the cause which induced it.—When occasioned by hæmorrhage, the languid state of the circulation permits the formation of coagula, which plug the vessels and arrest further discharge; and the loss of the voluntary powers causes the patient to fall in the very position which, of itself, generally restores the use of his faculties, by facilitating the transmission of blood to the brain. The indications are—*a.* To remove the cause of the affection; and, *b.* To recover the patient in the seizure.

17. *A.* For obvious reasons, the second intention often may be the first required, particularly when called to him in the attack. The patient should be placed in the horizontal position, and removed to an open and moderately cool air; and fragrant and cold water—lavender water, Cologne water, or simple water—may be sprinkled on the face, or rubbed on the palms of the hands, &c. In more profound cases, frictions of the limbs, epigastrium, &c. may be assiduously practised in a well-ventilated chamber; and the usual stimuli—æther, camphor, ammonia, &c.—given internally, in moderate or appropriate quantity, as soon as the patient can swallow. The recumbent posture should always be continued until recovery is complete.

18. When syncope supervenes upon *bloodletting*, the recumbent posture should constitute the whole means of restoration; for unless the operation has been very injudiciously resorted to, this will be sufficient for recovery. The use of stimuli in this case, will only increase the consequent reaction, and often aggravate the disease for which the depletion was employed. For syncope from *diseases of the heart*, a moderate and discriminating use of stimulants is often necessary; but they may be injurious if it arise from inflammation of the heart or pericardium. When it is caused by *hæmorrhage*, stimulants are very frequently hurtful, as they interfere with the consequent changes in the vessels, preventing a return of the hæmorrhage; but extreme cases and circumstances occasionally arise, rendering the use of stimuli indispensable.

19. If syncope occur *after parturition*, either from exhaustion of nervous power, or from hæmorrhage, internal and external stimuli ought not to be delayed. Swooning from hæmorrhage in the puerperal state always demands immediate and appropriate treatment, as it arises not only from the loss of blood, but also from exhaustion and the sudden removal of an accustomed pressure affecting more or less all the abdominal and thoracic viscera—from the combination of the three most powerful occasional causes of the affection. Besides, syncope supervening after the recumbent posture is assumed, is never devoid of danger; and the imperfect contraction of the uterus so generally connected with the production

of hæmorrhage, will not be remedied by the continuance of this state.

20. *Bloodletting* has been considered by some writers necessary to the cure of certain forms of syncope, especially by those who have confounded leipthymia with it, which is often benefited by depletions. ZACUTUS LUSITANUS relates a case in which he practised it largely; but the fainting was there evidently connected with disease of the heart,—bloodletting being often necessary in such circumstances, although requiring much discrimination, both as to its adoption, and to the mode and extent of employing it. In the actual state of syncope it can hardly be resorted to without risk. The practice in such cases must depend upon the inferred nature of the heart's disease. I was some years ago called by a neighbouring practitioner to a patient suffering from recurring syncope, vomiting of all ingesta, and severe pain in the epigastrium, with anxiety, &c. The disease was viewed as acute gastritis, and appropriate treatment adopted; it terminated, nevertheless, fatally in a few hours. On dissection, evidence of intense inflammation of the pericardium, particularly the part reflected over the heart, was found.

21. When *vomiting* supervenes during syncope, a speedy removal of the affection is the consequence, unless the syncope be, as in the preceding case, a sign of a most acute and dangerous disease, wherein bloodletting should be resorted to. When fainting arises from the quantity or quality of the ingesta, the exhibition of an emetic is generally beneficial.

22. The question has been proposed by BRAUSER, whether bloodletting should be persevered in or not, when it almost immediately causes syncope, without any evident cause? Such cases are not infrequent in practice; and I have met with the occurrence even where venæsection appeared most requisite, and the patient by no means fearful of its performance. In a case of this kind, which lately occurred to me, copious local depletion was substituted with great benefit; but in a still more recent case, the patient recovered by means of internal treatment, without bleeding in any way. The question, therefore, cannot be answered in a positive manner one way or the other, but where syncope takes place, bleeding is not required in the great majority of cases, and it may be injurious. At a time when bloodletting was viewed as the chief remedy in fever, and directed to be performed as early as possible in the disease, I had opportunities of seeing it practised in the cold stage, or previous to the development of reaction, of both the remittent and continued types; but it almost instantly, or before two or three ounces of blood had been withdrawn, produced syncope of a profound and serious kind, and proved manifestly hurtful. The results would have been very different had the operation been deferred to the stage of reaction; and hence, although instant syncope, or even faintness, upon bloodletting, is an indication of its injurious tendency, if persevered in at the time, yet a consequent state of action, general or local, may arise in a very short time, in which it will be borne to a very great extent without this affection resulting, and will prove most beneficial.

23. *B.* The removal of the causes of the affection, when these are of a constitutional or structural kind, must be attempted after recovery from the seizure. If it depend upon DEBILITY, the means advised in that article will be requisite; and in other circumstances, the treatment suitable to inferred pathological conditions should be practised, as pointed out in the places where such conditions are more especially and appropriately considered. — The prevention of a return of the affection will be most effectually secured by this procedure.

FEIGNING DISEASE. — CLASSIF. — DIAGNOSIS. — SYMPTOMATOLOGY.

1. Disease may be — 1st, *Pretended* or *simulated*, the person being in a state of health; — 2dly, *Artificially excited*, disorder being actually produced; — 3dly, *Exaggerated* in the description and appearance given of it, the patient being indisposed; — and, 4thly, *Artificially and intentionally increased*, or aggravated during its course. In these four modes, disease may be said to be feigned or simulated.

2. The objects desired to be accomplished by those who undergo the inconvenience, suffering, and moral degradation of feigning disease, are — *a.* To escape from being levied into the public services; — *b.* To procure a discharge from the public service; — *c.* To obtain both a pension and a discharge; — *d.* To enjoy the ease and comfort bestowed on the sick, and to escape from hard work, or unpleasant employment, mental or corporeal; — *e.* To obtain objects of desire, or to procure compliance with wishes or caprices; — *f.* To avoid punishment; — *g.* To excite compassion or interest; — *h.* To deceive.

3. The persons who feign disease with one or more of these intentions are — *a.* Soldiers and sailors; the former being usually called *malingers*, the latter *skulkers*; — *β.* Slaves and serfs; — *γ.* The lowest class of labourers, and mendicants; — *δ.* Members of benefit societies; — *ε.* Persons who have received accidental or intended injury, and desire to obtain increased compensation for it; — *ζ.* Prisoners for debt, or for civil or criminal offences; — *η.* Young persons of both sexes wishing to escape from the confinement of school and the labour of study, or longing for a return to their homes; — *θ.* The spoiled or indulged, who desire to excite interest, or to obtain a compliance with their desires; — *ι.* and lastly, Those who wish to accomplish objects of private or political ambition, or to gain particular ends. — Feigning disease has been resorted to with the last-mentioned view, very probably from the earliest times. AMNON the son of DAVID, ULYSSES, SOLON, the elder BRUTUS, the Roman CÆLIUS (“*Desit fingere Cælius podagram.*” — MARTIAL.), “HOTSPUR’s father, old NORTHUMBERLAND,” the Constable BOURBON, POPE JULIUS III., the Earl of ESSEX, and RALEIGH, grace this class of *malingers*.

4. Disease may be so artfully feigned in one or other of the modes just stated (§ I.), as to require the utmost discrimination and ingenuity to detect the imposture. It is obvious, as Dr. CHEYNE remarks, that the discovery of it will be most readily made by those who are the best physiologists and pathologists, and most accurately informed respecting the operation of medicinal agents. In doubtful cases, the practitioner should take into consideration the constitution, education, information, habits, and probable motives of the person; and examine more especially those symptoms which are counterfeited with the greatest difficulty, in respect not merely of their individual, but of their correlative, characters. The frequency and rhythm of the pulse, in connection with the temperature, colour, and humidity of the skin; the expression of the eye and face; and the fætor, colour, and consistence of the excretions; should especially arrest attention. A morbid appearance may be communicated to the excretions, and to the tongue and mouth; but a morbid fætor of the former, and various states of the latter, are counterfeited with great difficulty. The intelligent observer will infer much also from the manner of the simulator; from the consistency of the account given by him; and from the relation one symptom bears to another, in its seat, nature, or severity; and will be careful not to lead him to suspect that the reality of his ailments is for a moment doubted, until proofs of detection are complete. The circumstance of impostors always overacting their part, overloading their accounts with unnecessary details, complaining of their sufferings, and readily falling into the snare of enumerating incompatible symptoms, when a leading question respecting them is put, should not be overlooked. They are seldom desirous of obtaining medical aid, or of submitting to the treatment directed; and, in every case, strict attention should be paid to the exhibition of the medicines ordered, which ought never to be left in the possession of a suspected person. In doubtful, and even in real, cases of feigning, painful or even severe measures should not be inflicted, as in most instances, and especially in the public services, the mind of the impostor is made up to endure even torture rather than give in.

5. The importance of this subject in private

practice is greater than is commonly imagined; as one or other mode of feigning is often resorted to in civil life, especially among indulged females, in order to obtain compliance with their wishes, or to excite interest, or for the pleasure of deceiving; and, in such cases, the practitioner may lower himself in the estimation of the person attempting to impose upon him, by not detecting the cheat. At the same time he should be careful not to treat a person as an impostor unless the evidence is complete; for he will thereby injure himself in practice, and, in the public services, endanger the lives of those whom he wrongfully accuses. During the late war, when many went into the public services but scantily stored with medical knowledge, instances were not uncommon of persons feigning disease with success; and of others being treated and punished as impostors, who were actually suffering the complaints they made. In proportion, however, to the general advancement in medical science, such occurrences will be more and more rare; and, in recent times, numerous aids have been furnished, in very able papers on the subject, to those who may stand in need of them. In the following account of feigning disease, an alphabetical arrangement is adopted; indeed, it is the only one which the subject admits of:—

6. ABDOMINAL TUMOURS have been feigned by paddings worn in the dress; and by pushing the abdomen upwards in bed, or forwards when erect. Detection is easy in such cases, on examination of the naked person. When this is resisted, the inference is obvious.

7. ABORTION is simulated by staining the linen and body with blood, procured either by puncture of a vein in one of the extremities, or from the lower animals. Detection is difficult. The state of the pulse, the appearance of the mammæ, and of the countenance, and an examination *per vaginam*, may lead to more or less suspicion, but furnish no proofs of its occurrence.

8. ABSTINENCE, either total or partial, has been feigned in numerous instances. Many of the persons who have done so, have possessed the power of abstaining from food for a very long time; but deceit has been always practised, when total abstinence has been said to have been carried beyond a few days.—A woman was condemned for the murder of her husband in the 31st of Edward III. (*Med. & Phys. Journ.* vol. xxxi. p. 50.) She had the wisdom to fast in prison forty days, and was pardoned on account of her miraculous abstinence. ANN MOORE, who gulled the British public for some years in this way, and who really possessed the power of fasting for an unusually long time—eight or nine days, or nearly the whole period that a person can live without food—is said to have made a fortune by the imposture. Very attentive watching and much trouble are required in the detection of it; and wherefore should they be undertaken?

9. BLINDNESS—partial or total—is feigned chiefly by men in the public services, by mendicants, and by persons endeavouring to avoid conscription into the army or navy. *Amaurosis* is the common form assumed, but paralysis of the eyelids is also sometimes alleged. Amaurotic blindness, being characterised by a dilated and fixed pupil, may be detected by the absence of this sign, and by watching the patient without his know-

ledge. During the last wars, numerous French conscripts were exempted from service by simulating blindness, and using belladonna to dilate the pupil and render the iris inactive. When the simulator has had recourse to this means, even the reflected light of a mirror will not cause the contraction of the pupil.

10. CACHEXIA AFRICANA was formerly produced by the West Indian slaves, in numerous instances, by voluntarily adopting a practice usually caused by disease. It is often connected with disorder of the stomach at its commencement; and in this case, the practice of dirt-eating only aggravates the primary affection, or changes it into the true African cachexy. Whether the practice be the result of a morbid appetite, or adopted with the intention of affecting the health, or causing death, it may be detected by the exhibition of emetics, and on the examination of the stools, the egesta being washed. The only means which succeeded in preventing it, when resorted to with suicidal intention, was to cause the slaves to believe that decapitation would be performed on them after death, as they imagine that this operation prevents their return to their native country, and their migration to other states of existence.—(WILLIAMSON, in the West Indies; and myself in Africa.)

11. CANCER is said by MAHON, FODÉRÉ, and BECK, to have been feigned by mendicants and others.—A part of the spleen of an animal is glued on the part, with the smooth side to the skin, leaving on the outside the appearance of an ulcerated or diseased surface. PIERRE PIGRAY adduces an instance in which this mode of deception was attempted. His account leads to the inference that it was formerly practised on some occasions for the purpose of performing miraculous cures. Attentive examination of the part, and observing whether general signs of cachexia be present, are sufficient for detection.

12. CATALEPSY is not infrequently simulated by soldiers or sailors, and by hysterical and capricious females. It may generally be detected, partly by considering the circumstances in which it is observed, and the kind of persons who are affected, and partly by artifice. The use of powerful stimulants; letting fall a drop or two of a very hot or very cold fluid on the skin of the patient's neck; proposing the actual cautery whilst the pulse is being felt, and marking the effect; and suspending to the hand which has been stretched out a small weight attached to a string, which should be imperceptibly snipped, and observing whether or no the arm be suddenly thrown up, are the usual means of detection. The last method was resorted to by JOHN HUNTER, in St. George's Hospital.

13. CONCRETIONS of various kinds have been pretended to be passed from the bowels, urinary organs, vagina, and stomach, by soldiers and females. Cases of this kind are adduced by Dr. LIVINGSTON (*Edin. Med. Comment.* vol. iv. p. 452.), Dr. THOMSON (*Annals of Philos.* vol. iv. p. 76.), and Mr. DUNLOP (*Beck's Medical Jurisprudence*, p. 7.). The most superficial examination, and the rudest chemical experiments, will show the difference between the substances thus used for deception, and the ascertained nature of the morbid concretions occasionally passed from the bowels and urinary organs. One of the writers

in the *Cyclopædia of Practical Medicine* mentions a remarkable instance of deception practised by a young woman at Edinburgh, and continued from 1817 to 1830. She feigned during that time, hepatitis, epilepsy, amaurosis, aphonia, deafness, paralysis, gravel, anasarca, hæmatemesis, convulsions, gastralgia, dyspnœa, retention of urine, vomiting of substances resembling liver, bone, &c., and at last concluded by excreting bone from the vagina. Bone was first detected in the vagina in 1824, whilst introducing the catheter, and large quantities were passed, or extracted,—some even from the bladder. She was received into the hospital in 1825, and the bones which she passed were believed for a time to be those of an extra-uterine foetus. She was there detected by cutting off the supply, and discharged. She afterwards had recourse to the same practice, but at last varied it, and had an illegitimate child in 1828.

14. DEAFNESS AND DEAF-DUMBNESS are simulated by those who wish to escape from the army or navy, or from criminal trials, and by mendicants. They generally lose their hearing suddenly; whereas real deafness is gradual, or the consequence of severe illness. The expression of the countenance and a change in the pulse often betray the impostor when something of great importance is said in his hearing. But some are prepared for this, and are even unmoved by very sudden noises. MR. DUNLAP states, that a soldier feigned deafness so well, that firing a pistol at his ear produced no effect; but on the experiment being tried after he had been put to sleep by opium, he started out of bed. Those who feign dumbness, are generally unaware that if a person has acquired the use of speech, he never can become dumb, however deaf he may be. The really dumb acquire an expression of countenance and gestures which are assumed with great difficulty, and few have sufficient art and perseverance to counterfeit deafness and dumbness, so as to avoid detection for any length of time. Some have attempted even to cause deafness, by introducing solid bodies into the ear, or by exciting inflammation of it by irritating matters. Honey and various other substances have been employed so as to simulate *otorrhœa*. The organ and the discharge from it should therefore be carefully examined.

15. DELIVERY has been pretended, with an obvious intention, after artificial abdominal enlargement and sudden subsidence of the tumefaction. In this case the external parts of generation are moistened by procured blood, and the child of another substituted as the female's own. This cheat can be detected only by examining *per vaginam*. Soon after real delivery, the vagina will be relaxed as well as the os uteri; the latter tumified and tender, and the lochial discharge flowing. But these signs will become less evident, the longer the time that has elapsed; and, after nine or ten days from parturition, they cannot be depended upon; but the well-known state of the integuments of the abdomen, and the appearance of the mammae, will aid detection.

16. DROPSY has been simulated by French conscripts, who have been said to have actually injected water into the cavity of the peritoneum, and thereby produced factitious ascites.—Anasarca of the extremities has been caused by

ligatures artfully concealed; but the imposture will be detected upon strict examination of the naked body, and by the absence of a leucophlegmatic or cachectic appearance. Cushions fitted to the abdomen, and padded clothes, are the modes resorted to by mendicants; but these require no remark. Instances are mentioned by MANGETUS, SAUVAGES, and others, of *chronic dropsy of the head* being simulated by mendicants, who have daily blown air under the scalp of children through a small perforation at the vertex, until the scalp became enormously distended.

17. DYSENTERY and CHRONIC DIARRHŒA are often feigned by soldiers and sailors, particularly in warm climates; and are sometimes actually produced by their using irritating substances for the purpose. MR. COPLAND HUTCHISON has seen even a fatal result follow such practices. He ascertained that vinegar and burnt cork were often used to cause the disease. Suppositories of soap, and irritating substances introduced into the rectum, have also been employed to cause mucous discharges (CHEYNE); but drastic purgatives are more frequently taken in sufficient quantity for this purpose. The dysenteric evacuation is simulated by breaking down the fecal evacuation in the urine, and mixing with it the blood procured by pricking the gums. The imposture is detected by the cleanness of the linen; by obliging the patient to use a night-chair, and by watching his proceedings.

18. EMACIATION—partial or general. *General emaciation and debility* are sometimes occasioned with the view of avoiding some disagreeable service, or to be sent home from foreign service, or to procure change of climate. Abstinence from food and sleep, the frequent use of purgatives or diaphoretics, especially antimony, and excess in spirituous liquors, are the means commonly resorted to. Wasting of a limb is caused chiefly by mendicants, by means of continued compression; and the diagnosis between artificial and real wasting is often very difficult. Detection must depend upon a strict examination, and a variety of considerations thereby furnished to the duly qualified examiner.

19. EPILEPSY is very frequently feigned by mendicants, by sailors and soldiers, and occasionally by females to serve particular ends. In such cases it is proper to notice whether the person falls to the ground without regard to the situation or place; whether the face be livid, the pupil fixed, the spasm and convulsions general, the pulse altered, the insensibility complete, the mouth distorted and frothy; and whether sopor follow the fit, passing into heaviness, vertigo, and exhaustion, as all or most of these symptoms are absent, or imperfectly evinced in the simulated disease. The opportune appearance of, and selected situation for, the feigned paroxysm, the partial or successive production of the muscular actions, the sensibility of the iris, the abrupt termination of the seizure, and the absence of injury to the tongue, should also be taken into account. Foaming at the mouth is sometimes imitated by means of soap kept in it; but it is generally overdone in this case. The real epileptic is desirous of concealing his infirmity; whilst the simulator talks of his disease, and never endeavours to avoid publicity. It is chiefly, however, by artifice that feigned epilepsy can be fully

detected. DE HAEN, observing the sensibility of the pupil in a girl who feigned epilepsy to avoid work, suspected the imposture, and desired the attendants to place her in an erect posture, and to chastise her severely if she fell. She confessed the cheat. A beggar in Paris, who often fell into fits in the streets, was placed on a truss of straw, ostensibly to prevent him from sustaining injury. When in the midst of the paroxysm, fire was set to each corner of his bed, and he sprang up and fled. SAUVAGES was called to a female who imitated the fit remarkably. He inquired whether, on the access of the paroxysm, she felt pain extending from her arm to her shoulder, and thence to the opposite thigh. She said that she did, and was detected. MR. COPLAND HUTCHISON introduced some Scotch snuff up the nostrils of a man whom he suspected of feigning a fit. It induced a fit of sneezing, and epilepsy was not afterwards heard of. Dropping alcohol into the eye (CHEYNE), the introduction of nauseating substances into the mouth, proposing very painful or dangerous means of restoration in the patient's hearing, the dread of the actual cautery, directing boiling water to be poured over the legs, and actually pouring very cold water, have severally been recommended. DR. CHEYNE states, that in the case of a soldier, a table was placed upon another, and the simulator laid, in the midst of his fit, on the former. Dread of the fall terminated the convulsions. In doubtful cases, particularly in the public services, the medical man should be cautious in giving an opinion, and should never sanction punishment. DR. CHEYNE and other experienced writers state, that they are "in possession of sufficient evidence to prove that real epilepsy has often been considered feigned;" and they might have added—punished accordingly. But these occurrences, however frequent in past times, are not likely to take place often in future.

20. FÆCES.—Incontinence of fæces is sometimes feigned. It is detected by examining the sphincter ani, according to the recommendation of DR. CHEYNE; who directs that, if it should contract upon the finger, opium and solid food should be prescribed, and a watch set over the person. If he pass solid fæces in bed, he will be a fit subject for punishment.

21. FAINTING and SWOONING are simulated by medicants, by hysterical or indulged females, and by sailors and soldiers in order to escape punishment; but the nearly or entirely absent pulse, the scarcely perceptible respiration, the collapse, coldness, and paleness of the countenance, and cold sweats, with coldness of the extremities, are not easily produced at will. Ligatures or pressure have been used to suppress the pulse, and washes applied to the face to produce paleness; the means of detection should therefore have reference to such artifices.

22. FEVER is more frequently produced artificially, than feigned. Ague is the type selected when feigning is attempted. The exertions, however, necessary to simulate the rigors of the cold stage, will generally be found to be productive of the sweating stage instead of the former. Cantharides, and various stimulants, are usually taken to induce febrile symptoms; and a temporary acceleration of pulse is often occasioned by both sailors and soldiers, just before the phy-

sician's visit, by striking the elbow against any hard substance. Some persons acquire a power of accelerating the heart's action at will. Emetics are sometimes also resorted to, to make the deception more complete; and the tongue is artificially coloured by chalk, pipe-clay, brick-dust, tobacco, brown soap, &c. When suspicion is excited, the pulse should be examined a second time on leaving the patient, and preferably in the carotids or temples; the state of the excretions being particularly attended to. Cases of feigned fever are generally ephemeral, and a day or two of close examination generally leads to detection.

23. GASTRIC AFFECTIONS, especially *gastralgia* and attacks of *vomiting*, are sometimes simulated. The former is detected with great difficulty, and chiefly from collateral circumstances. *Vomiting* is generally produced by having recourse to the common emetics, or to tobacco, particularly the latter, on account of its depressing influence on the nervous system and circulation; and by pressure on the stomach (C. HUTCHISON). I met with an instance, some years ago, where it was induced at will, by the action of the abdominal muscles, without even the aid of irritating the fauces. In such cases, the state of the appetite and the appearance of the evacuations should be examined; for, unless where tobacco has been taken to disorder the stomach, the former is but little impaired. In the case of vomiting at will just mentioned, the person had no sooner emptied his stomach, than he proceeded to replenish it again with an appetite. Not only is vomiting produced, but further deception sometimes is attempted by introducing various foreign substances into the matters ejected. A singular case in which a girl was said to have brought up the larvæ of insects and reptiles from her stomach, is recorded in the *Transactions of the Dublin College of Physicians*. It afterwards, however, was ascertained to have been a well-managed deception.

24. HÆMORRHOIDS are sometimes simulated; the appearance of the hæmorrhoidal tumours being imitated by means of small bladders filled or tinged with blood, and partially introduced into the rectum (PERCY and LAURENT). Simple discharge of blood from the anus is more easily feigned; and the deception is detected with greater difficulty.

25. HÆMORRHAGES from the *Stomach*, or from the *Lungs*, are often feigned. In order to imitate *Hæmoptysis*, cough is pretended, and the saliva coloured by pricking, scratching, or sucking the gums; or by holding Armenian bole, brick-dust, vermilion, &c. in the mouth. An attentive examination of the sputum, and of the physical and rational symptoms, will generally lead to detection. *Hæmatemesis* is often feigned by swallowing bullock's blood, and soon afterwards by inducing vomiting. If the quantity taken be considerable, vomiting will often follow without any aid. Instances of deception practised in this way are mentioned by SAUVAGES, METZGER, and BECK. A close investigation of the symptoms, and, if suspicion be occasioned, a strict surveillance, will generally prevent a continuance of the imposture.

26. HEART-AFFECTIONS have been simulated, in order to escape from the public services. MM. PERCY and LAURENT state, that a ligature has

been found so firmly bound around the neck, as to cause a livid and swollen countenance, and disorder the heart's action. Dr. QUARRIER and Mr. COPLAND HUTCHISON ascertained, that white hellebore was often used by sailors to produce this effect; vomiting, purging, syncope, tremors, and nervousness, followed by palpitations, being the usual consequences of a large dose of this substance. Mr. DUNLOP states, that death was occasioned in one instance by the use of hellebore with this intention.

27. HEPATIC DISORDERS are often feigned by soldiers in warm countries, particularly in India; and by officers and others desirous of returning to Europe. If any doubt of the reality of the complaint exist, the person should be undressed, and carefully examined by percussion and the stethoscope. The absence of enlargement in the region of the liver, the complexion, and appearance of the surface and limbs, and the state of the pulse and respiration, are the circumstances which should chiefly be considered. It ought not, however, to be overlooked, that most serious disease of the liver may exist without enlargement; and this viscus may be considerably enlarged, and even rise up into the right thorax, without being felt below the ribs. Hence the propriety of having recourse to percussion and auscultation in the investigation, especially when other proofs of disease are wanting.

28. HERNIA and HYDROCELE have been simulated by blowing air into the cellular membrane of the serotum. Mr. C. HUTCHISON met with an instance of hernia being feigned, by elevating the testes to the external abdominal rings. Detection in cases of this kind is quite easy.

29. HYSTERIA is not infrequently feigned. Dr. DUNGLISON directs sternutatories to be employed; but the affection may be real, although they produce their usual effect. Detection is by no means easy, especially when an intelligent female simulates this complaint. In a case to which I was lately called, the moral circumstances and the symptoms induced me to infer deception; and I accordingly took my leave, by simply stating, in the patient's hearing, that, if recovery was not complete in a few minutes, the affusion of cold spring water over the head and neck would certainly have the desired effect. It should, however, be recollected, that females who are really hysterical are the most prone to feign disease; this affection and the desire to simulate others frequently arising from the same cause, viz. uterine irritation.

30. JAUNDICE, notwithstanding the difficulty of the attempt, has been successfully simulated, particularly in France, during the late war. Conscripts employed an infusion of turmeric to tinge the skin, muriatic acid to give the evacuations a clay-colour, and rhubarb to heighten the colour of the urine. But the white of the eye cannot be changed by art, although smoke has been tried for this purpose. Washing the surface and preventing access to the materials of deception are the chief means of detection.

31. INSANITY in some one of its various forms — but most frequently mania, melancholy, and idiocy — is frequently feigned; and detection is by no means easy. There can be no doubt that, in the public services, pretenders often gained their ends; and that the really afflicted were some-

times treated as impostors. Nor can this be a matter of surprise, when the great difficulty of discrimination is considered. In the present day, madness is most commonly feigned with the view of escaping from the punishment due to crime; and the responsibility of the medical examiner is consequently great. He should, therefore, have every facility afforded him, and take sufficient time to the investigation, that he may arrive at a correct conclusion. He should endeavour to obtain from the individual a full account of himself; mark its consistency, and place an intelligent watch over him. The expression of the countenance, and of the eye; the gestures and manner; the state of the tongue, the appetite, and the evacuations; and especially the duration, continuance, or frequency of sleep; ought to be carefully observed. Certain expressions of countenance and gestures are so peculiar to the insane, that the experienced observer will infer much from them. Pretenders generally overact their parts; assume the more violent or disgusting forms of mania; do not maintain the deception when they believe themselves unobserved; recommence it in the society of others; and possess not the power of prolonged abstinence from sleep and food so generally observed in the truly insane. Sound sleep soon overpowers the pretender, whereas the insane are remarkably watchful; sleeplessness to a distressing degree often preceding the disease, and always attending it throughout, for much longer periods than can ever be endured by a person in health.

32. The insane, during remissions, are desirous of being considered free from the malady, and often assiduously endeavour to conceal whatever may betray them; but simulators seldom carry their deception thus far. The real malady usually commences with slight disorder of the common modes of thinking and acting; and advances slowly through some hallucination, until at last it is either fully developed, or is suddenly exasperated. The feigned disease, on the contrary, presents not this course; is not preceded by sleepless or restless nights, and by a continued consideration of one topic; but appears at first in its full violence. The existence or non-existence of the causes of insanity, of previous attacks, of pre-existing eccentricity of manner or thought, of hereditary tendency, of antecedent affections of the brain, of injuries of the head, &c., the character of the individual, and the motives for feigning, will also be considered by the physician. Care should be taken not to infer deception, because the motives for it are apparently strong; for the circumstances constituting the motives may be the causes of the real malady. The costive state of the bowels; the large doses of medicine necessary to move them; the comparative insensibility of the stomach to tartarized antimony; the generally more frequent pulse, and the sudden and extreme irritation on any contradiction, observable in the maniacally insane; should not be overlooked, as they hardly admit of being feigned. Their disregard of the decencies, comforts, and affections of life, ought also to be taken into account; for, although these signs are often also simulated, deception in respect of them is seldom carried so far as in the real malady. A person even of pure character, when truly insane, will often use the grossest

language, practise the greatest indecencies and brutalities, and evince the bitterest dislike of, and malice to, his friends; but simulators exhibit those symptoms only when they believe themselves watched, or before others. Dr. HASLAM remarks, that the *melancholic states* of insanity are feigned with greater difficulty than the maniacal; the one presiding principle, the ruling delusion, the unfounded aversions, and causeless attachments, the peculiar look, the solemn dignity, and the associations characteristic of the former, can never be simulated so as to deceive the experienced observer. *Idiocy* is most easily feigned; yet there are always a hesitation and reflection observable in the discourse of the pretender; his disordered ideas not succeeding each other with the same rapidity as those of a person whose understanding has been really destroyed. The simulator will also, according to Dr. MARC, repeat the same ideas, and often the same words, in order to prove his madness, that he is requested to repeat, whereas the truly insane will wander incoherently from what he is desired to utter. In this form of insanity, the patient is always pusillanimous and submissive, unless during impetuous excesses, which only sometimes occur; and memory and conception are both defective.

33. It may sometimes be proper, if suspicion exists, to mention some severe remedy, or to threaten punishment. The really insane never heed these; but those who feign, will often discover by the change in the pulse, or by looks or actions, the emotions thereby induced. ZACCHIAS states, that a physician ordered, in the hearing of a person whom he suspected of deception, that he should be severely whipped; inferring that the external irritation might be useful if the disease was real, or too severe a test if feigned. The threat was sufficient. FODÉRÉ, on leaving a female who had long succeeded in simulating insanity, said to the keeper, within hearing of the patient, "To-morrow I shall again visit her; but if she continue to howl, if she be not dressed, and her chamber not put in order, you must apply a red hot iron to her neck." This was sufficient. The very treatment most conducive to the recovery of the really insane, is the most intolerable, if persisted in, to the simulator; who is often all at once cured upon hearing of his being about to be sent to an asylum, or of a continued and rigorous recourse to solitary confinement, low diet, and repeated counter-irritation.

34. LAMENESS is often feigned by sailors, soldiers, mendicants, and convicts, by pretending contractions of the muscles, deformity, the effects of fractures, and by introducing sharp bodies under the skin. For pretended *contractions* of muscles or joints, a tourniquet may be placed above the joint, and so closely drawn as to render the muscles incapable of acting, when the joint will become moveable. The emaciation of the limb in these cases is no proof of their reality, as it necessarily proceeds from disuse of the limb. — Previous *fractures* of bones is often alleged; but the cheat is readily detected on minute examination. — *Malformation*, particularly curvatures of the spine, elevation of one shoulder, inversion of the feet, and shortness or distortion of a limb, are sometimes simulated. There can be little difficulty in detection, on a careful examination of the naked body. Pretended distor-

tion of a limb may be ascertained by the use of the tourniquet, or by straightening it, whilst the simulator's attention is withdrawn from it, as was done by Mr. C. HUTCHISON in a case which occurred to him. Instances have been met with of females who caused serious swellings and abscesses by introducing a number of needles into the parts.

35. NEURALGIC, RHEUMATIC, and other PAINS are very frequently simulated; and detection is very difficult, as it is next to impossible to prove the absence of pain. Inconsistencies in the patient's account of his case, and contradictions into which he may be readily led by an artful examination, are the chief means of detection. Pain is seldom very severe or prolonged, without being attended by certain symptoms, according to its situation. If it affect the joints, swelling, redness, stiffness, &c. are usually the result; if it occur in any part of the abdominal cavity, the functions of digestion, assimilation, or excretion will be disordered; if it affect the thoracic organs, circulation or respiration will be deranged; if it occur in the head, loss of sleep will, at least, be the consequence. The inference should depend much upon the kind of pain complained of, upon its continuance or recurrence, and the nature of the phenomena attending it. If violent pain is stated to be present, and the patient, notwithstanding, has a good appetite, sleeps well, and does not lose flesh, we may doubt its reality. The effects of remedies should also be taken into the account, as well as the patient's desire of, or objection to, those which are of a severe kind. But the most severe pains may long exist, even in external parts, without affecting their appearance; and be referred to internal organs, without materially deranging the functions. Several instances of this kind have come within my own observation. These have been usually called neuralgic; and have often disappeared for a time, either during treatment, or without the use of any means. Many of the reputed cures of these would have taken place without any remedy whatever; but, to whatever cause the recovery is attributable, the return of the pain in some form or degree, is generally observed, although of this as little as possible is said by narrators of extraordinary cures; and sometimes a return of the complaint is the least unfavourable occurrence, — a more dangerous or even fatal malady taking its place, especially in the rheumatic and gouty diathesis.

36. Cases have occurred, which have caused suspicions of feigning, and yet the results have shown most serious internal disease. A female, some years since, consulted a number of physicians respecting a most violent pain in the left side and loins, extending upwards to the left mamma. One considered it neuralgic, another hysterical, a third uterine irritation; a fourth deception, probably connected with hysteria; and, lastly, it was attributed to spinal irritation. The appetite continued good, the urine appeared healthy, and there was no emaciation. After many years of suffering, the lady died; and there were found (what, indeed, might have been expected) a great number of calculi in the uriferous ducts and pelvis of the left kidney. — A celebrated preacher and theological writer long complained in a similar manner. The urine was abundant, and of a good colour, and hence dis-

ease of the kidney was not suspected by the numerous eminent men whom he consulted; but this organ was, nevertheless, found after death, filled with calculi. I have met with two or three instances of the most severe pain, recurring at irregular intervals, in a particular joint — in the left shoulder joint in one case, and in the right knee in another — without any apparent local or constitutional disturbance; the tongue being clean, the bowels regular, the appetite good, and the flesh and strength undiminished. An ointment, with a large proportion of veratria, was employed for some time in one of these cases, without benefit. The most successful means, in both, were such as improved the digestive and excreting functions. These cases, in circumstances admitting of the least suspicion, might have been considered as feigned.

37. I have no doubt that formerly, when the pathology of the spinal chord and its membranes was less attended to than now, many very severe affections, occasioned by changes in this quarter, were viewed as fictitious. — I lately attended an intelligent tradesman, advanced in life, who long complained of severe pains in the thorax, darting through both sides, and often backwards to between the shoulders. They were occasionally most violent, and fixed themselves for a time in one place, and then in another, of this cavity. The functions of circulation and excretion were unaffected, but the respiratory actions were sometimes disturbed. One day he was unable to get out of bed; and another he came down to his parlour. His complaints were considered chronic pleurisy, adhesions of the pleura, rheumatism of the thoracic muscles, &c. When first called to him, I examined the thorax by auscultation and percussion. The sounds furnished by both were perfectly healthy. The liver was thought to rise rather high; and the stools were deficient in bile. Chronic disease of the liver was, therefore, suspected. Upon extending the examination to the spine, two of the spinous processes of the upper dorsal vertebrae were found very prominent, and pressure in this situation caused great pain. The treatment was directed accordingly, and amendment took place. These cases evince the importance of a very minute and extended examination, in ascertaining the cause of pain, and, consequently, of proving its reality. When severe pain is complained of by females in any external or internal part, an opinion as to its reality or nature should not be given until the spine is carefully examined, and the state of the uterine functions inquired into. The existence or non-existence of tenderness, pain, or fulness in the hypogastric, iliac, and sacral regions, indicating disease of the uterus or ovaria, ought also to be ascertained; for if the least sign of disorder in any of these situations be detected, we ought not to infer deception, although it must be admitted that exaggeration, and even deception, may be practised nevertheless.

38. OPTHALMIA was not infrequently produced by soldiers and conscripts during the last war, by means of corrosive sublimate, powdered alum, quicklime, acids, salt, tobacco, and various acid powders and mechanical irritants. The extreme rapidity of the inflammation, especially as respects its invasion of the conjunctiva oculi and cornea, and the circumstance of the right

eye only being affected, should excite suspicions. The chronic forms of ophthalmia were also excited and kept up by extracting the eyelashes and applying irritants to the edges of the eyelids. When entire seclusion of the suspected patient cannot be obtained, as in the navy, the recommendation of Mr. C. HUTCHINSON to use the strait waistcoat should be adopted.

39. PALSY and SHAKING PALSY are not often feigned. If, with the loss of motion, or the continued agitation of a limb, or one half the body, the general health appears to be good, and the excretions natural, a watch should be set upon the patient, and his actions observed when he thinks himself unnoticed. The cold affusion, electric shocks, moxas, and the actual cautery, will often have a wonderful effect in suspicious cases. Even the threat of having recourse to these means has been sufficient. — In cases of simulated paralysis, detection may be easily accomplished by causing sleep by opium, and then ticking, irritating, or pinching the motionless extremity. If the disease be feigned, the limb will be retracted or withdrawn: and, upon first wakening, it will often be used before the patient recollects himself.

40. POLYPUS of the Nose has been often imitated, according to MM. PERCY and LAURENT, by French conscripts, who have succeeded by introducing the testes of cocks, or the kidneys of hares or rabbits, into the nostrils, and retaining them there by means of sponge to which they had been fastened.

41. PREGNANCY is often pretended, to gratify the wishes of a husband or relations, to increase interest, to extort money from a paramour, to deprive a legal heir, to delay the execution of punishment, and to avoid labour. A careful examination of the areolæ, of the mammae, of the umbilicus, and of the *os uteri*, will generally lead to detection, at least in the more advanced months. (See PREGNANCY.)

42. PULMONARY DISEASES are not often feigned; but I have met with instances — two in females — in which slight symptoms have been exaggerated into the appearance of dangerous disease, particularly in the description of them, in order to accomplish particular ends. In such cases, the patient has a frequent and short respiration, and a hacking cough, with little or no expectoration; complains of the pain on coughing or taking a full inspiration, and of night sweats; evidently desires to be considered very ill, but is averse from medicine: as he considers it of no use; and even resorts to various means to produce emaciation, particularly vinegar, the oxides of copper, cream of tartar, tartaric acid, &c. The state of the pulse, the sounds produced by auscultation and percussion; the apparent despondency, instead of the continued and unwearied hopes of the patient, characterising the real disease; the marked reluctance to have recourse to issues, setons, or counter-irritants; and an enquiry into the wishes of the patient as to regimen, &c. are the chief means of detection. In private practice, the physician should endeavour to ascertain whether or no the treatment directed is strictly followed, particularly the insertion of issues, setons, &c.; for if these be not adopted after a confident recommendation of them, strong suspicions of deception should

be entertained, and he should immediately withdraw.

43. **RECTUM.** — *Prolapsus and Fistula of the Rectum* have both been simulated by conscripts and persons desirous of escaping from the public services. AMBROSE PARÉ, PERCY, and LAURENT met with instances in which a portion of sheep's gut, or the urinary bladder filled with blood, had been partially introduced up the rectum in order to imitate *prolapsus*. *Fistula* has been actually produced by making an incision near the verge of the anus, and introducing into it an acrid tent, particularly the root of white hellebore (DUNGLISON.)

44. **RHEUMATISM and LUMBAGO** are often feigned by soldiers and sailors. Where they are complained of, without swelling of joints, or acceleration of pulse in the evening, or increased heat of the affected part, wasting of the limb, disorder of the digestive and biliary organs, or loss of the appetite and looks, suspicion should be excited. Dr. CHEYNE remarks, that those who feign this disease, "give a glowing account of their sufferings, alleging that they have entirely lost the use of the part affected, which seldom happens in genuine rheumatism. There is, for the most part, no adequate cause assigned for the complaint; no relief from remedial treatment acknowledged; and, while real rheumatic affections are aggravated by damp, the impostor complains equally at all times." (See § 35.)

45. **SIGHT.** — Defects of this sense are frequently feigned. *Short-sight* may not only be pretended, but it may actually be occasioned by the use of concave glasses, in order to avoid military service. Those who are truly near-sighted, frown or knit their brows habitually, when looking at objects beyond the range of distinct vision, and the *crow-feet* wrinkles at the outer corners of their eyes become early marked. MM. FODÉRÉ, PERCY, and LAURENT advise that persons claiming exemption on this account should be caused to read with concave glasses, the book being held at a proper distance; and without them, the book being put close to the eyes; if they cannot read distinctly in both cases, the imperfection is feigned. — *Night-blindness*, or intermittent blindness (hemeralopia, nyctalopia), is often simulated by sailors and soldiers serving in warm climates, where the affection is common; and it is detected with difficulty. The deception is practised in order to avoid night duty; and has been put a stop to by associating a blind man with one who can see, in the various works carried on during night, and when the sentries are doubled. (CHEYNE.)

46. **SOMNOLENCY, or SOPOR**, has been feigned with the utmost pertinacity, in order to obtain a discharge from the public services, or to answer purposes of revenge, as in the instances recorded by Dr. HENNEN and Mr. DEASE. As cases of sopor sometimes occur, care should be taken to distinguish between the real and simulated. The former is seldom, or perhaps never, unconnected with some cause of exhaustion operating chiefly on the nervous system, or without antecedent signs of mental and physical debility, particularly defect of memory, hesitation of speech, remarkable languor, &c. I lately attended, with Mr. BUSHELL, a gentleman about sixty years of age, who continued for many weeks in a state of sopor,

interrupted only by being talked to loudly, or by taking food. When thus roused, he yawned, answered slowly, and instantly fell into a quiet sleep, unattended by any unnatural respiratory sound. He recovered slowly by the use of tonics and stimulants, and the occasional exhibition of stomachic purgatives. No cause but exhaustion of nervous and cerebral power could be assigned for the disease. Such cases, however, most frequently follow injuries of the head, attended by pressure on the brain, or the slow development of tumours within the cranium. Dr. G. SMITH mentions the case of a soldier who feigned a state of insensibility, and resisted every kind of treatment; but on proposing, in his hearing, to apply red-hot iron, his pulse rose, and amendment rapidly followed. A singular case of feigned sopor is detailed in the *Edinburgh Annual Register* (vol. iv. part ii. p. 159.). A soldier 18 years of age, confined for desertion, lay, apparently insensible, from the end of April to the 8th of July, 1811. Electric shocks, the application of snuff to the nostrils, pins thrust under his finger-nails, and other stimulants, failed to rouse him. The sopor being thought the consequence of injury, the scalp was divided in order to ascertain the existence of depression, and the bone even scraped! yet no complaint was made. The case was viewed as hopeless, and the man dismissed. Two days after his discharge, he was seen cutting wood some miles from home. But wherefore should a depression of the cranium be hunted out by dividing and drawing back the scalp and scraping the bone? One would expect that some tolerable signs of its existence should have presented themselves before such serious measures were resorted to. Can we be surprised at detection failing in such hands?

47. **TYMPANIC and EMPHYSEMATOUS AFFECTIONS** have been simulated, by introducing air into the digestive canal, and by inflating the cellular tissue, in the manner already stated (§ 28). MM. PERCY and LAURENT mention the case of a conscript who simulated an immense tympany by swallowing air; and Dr. CHEYNE states, that this affection was apparently caused by a number of men in the 84th regiment. The pulse, tongue, and excretions were natural, but pain in the region of the liver, and over the abdomen, which was distended and tympanic, with insatiable thirst, were complained of. Deception being suspected, they were required to take a cupful of a solution of the sulphate of soda in weak tobacco water, every four hours, until it operated. Recovery was speedily effected by means of this detestable medicine; but sixteen men had succeeded in procuring their discharge before this treatment was adopted. Dr. G. SMITH states, that wonderful cures were often effected in military hospitals by a medicine composed of salts, aloes, and assafoetida, given frequently in small quantities, so as to keep the taste in the mouth. The substances used to produce this tympany seem not to have been fully ascertained. It was ascribed to the use of large quantities of chalk and vinegar.

48. **TUMEFIED LEG** is excited by means of an artfully concealed ligature, and keeping the extremity in a hanging posture. The writers on this subject in the *Cyclopaedia of Practical Medicine* state, that a case of enormous enlargement

of the thigh and leg, resembling elephantiasis, was sent home from India to be discharged. A ligature was discovered, and, upon its removal, the swelling gradually subsided. — The detection and prevention of such cases cannot be difficult.

49. **ULCERS** artificially caused were remarkably frequent in both navy and army, during the last war. They were generally produced upon the legs by various caustics or irritants, by friction with sand, by quicklime mixed with soap, by compression with metallic or other bodies, and by mineral acids. Arsenic, corrosive sublimate, tobacco, &c. have also been used for this purpose. Mr. C. HUTCHISON found a halfpenny between the muscles of a leg which he removed in consequence of extensive caries of the tibia following artificially formed ulcers. Intentional ulcerations are distinguished from the real, by their borders being less callous, their surfaces more superficial and less painful, and their disposition to heal, when secured against tampering, much greater, owing to their not originating in, or accompanying, constitutional disorder, as in the case of real ulcers. — In order to prevent this species of deception, Mr. C. HUTCHISON had recourse to a wooden box, in which he locked up the whole limb; all other means, as marked or sealed bandages, &c., having been found insufficient against the ingenuity of malingerers.

50. The URINE presents various disorders in respect of its characters and of its excretion, which have been artificially produced or feigned by persons desirous of escaping from the public services, and by hysterical females. — *Incontinence of Urine* was often simulated by sailors and soldiers. The circumstance of this disorder occurring frequently in this class of persons, who are mostly young, or in the vigour of life, should excite suspicions of its reality. The simulator generally chooses the circumstances and place suitable to his purposes in allowing the urine to escape. LAURENT and PERCY state that the *glans penis* is always pale and shrivelled in real incontinence, and that the urine never comes away in a stream. M. FODÉRE finding that this complaint was becoming epidemic in a regiment, and that blistering the perinæum and other means did not cure it, directed the penis of every patient to be tied, and the knot sealed, none but the person guarding them being allowed to remove the ligature. The penis was observed from time to time, to ascertain whether or no distension above the ligature existed, and whether, when it was removed in order to urinate, the discharge took place *guttatim*, as in real incontinence, or in a stream. The expedient succeeded, and the epidemic vanished. (Vol. ii. p. 481.) PERCY and LAURENT prescribed twenty lashes to the loins, with the avowed object of exciting the weakened organs. It was unnecessary to direct it to a second case. An army surgeon directed a cold plunge-bath twice a day with equal success; and Mr. HUTCHISON, Mr. COMYNS, and Dr. HENNEN caused a strong opiate to be given at night, and the length of time the urine was retained during sleep to be watched; for, in real incontinence, the urine passes away after a short time under all circumstances. The patient may also be caused to undress and stand before the medical man at the time when he states that his urine

usually passes off. In cases of feigning, the abdominal muscles will be seen contracting in order to expel it.

51. *Bloody Urine* has been simulated by the ingestion of beet-root, madder, the extract of logwood, the fruit of the prickly pear, the Indian fig, &c. But blood is more frequently mixed with the urine. PERCY and LAURENT state, that conscripts have injected blood into the bladder, in order to imitate hæmaturia. This disease has even been occasioned by having recourse to cantharides. A boy in Staffordshire, in 1617, having accused a woman of bewitching him, feigned various maladies; and, amongst others, the excretion of *black urine*. The wisdom of our ancestors condemned the woman to be burnt, as was usual in such cases; but the Bishop of the diocese, suspecting imposture, caused the boy to be watched, when he was detected dipping cotton in ink, and afterwards introducing it within the prepuce, in order to give the urine which he publicly voided its dark colour. (*Mem. of Literature*, vol. iv. p. 357.)

52. The excretion of *Gravel*, and of other substances, has likewise been feigned. In all such cases, as well as the foregoing, the person should be made to urinate in the presence of the physician. The real existence of gravel is ascertained beyond doubt, by close inspection and chemical analysis. — *Strictures* have also been feigned; but the passage of a bougie will always ascertain their reality in the hands of an expert surgeon — *Suppression and Retention of Urine* have been pretended; but most frequently by convicts, and hysterical females. The introduction of the catheter, and a strict watch will generally show the state of the case.

53. **UTERINE DISEASES** have been feigned and exaggerated, and I believe more frequently than is commonly supposed. It was attempted in one case in which I was some years ago consulted; but the object becoming apparent I withdrew. This kind of simulation is sometimes adopted with an evident motive, as dislike of a husband, &c.; but in other cases the object is not so apparent. Dr. THOMSON, of Edinburgh, mentions an instance of a female in a respectable station, who pretended to pass vesicular bodies resembling hydatids from the vagina. They were ascertained to be prepared from the intestines of a pig, and were made to resemble a string of beads.

54. **VARICOSE VEINS** have been caused by ligatures or pressure made in the course of the larger trunks. They may also be aggravated, when already present, in a similar way. Attentive examination, and the means advised for ulcers (§ 49.) will generally detect the deception, and prevent it.

55. **WOUNDS** have been both pretended, and inflicted intentionally. The feigning of wounds has been sometimes practised to avoid the danger of battle, or to be mentioned in despatches. Means which may occasion the appearance of a contusion, as abraiding or discolouring the surface, are chiefly resorted to. Detection will depend upon attendant circumstances and the acuteness of the surgeon. Mutilations, or intentional wounds, are more commonly resorted to, in order to avoid conscription into the public services, or to obtain pensions or a discharge. They are sometimes also practised by slaves, mediceants, and revengeful persons. And wounds

and injuries involuntarily received, have been aggravated, and their healing interfered with, to answer particular purposes. Detection in many instances is difficult, but it will be necessary to consider the possibility of the patient having inflicted the wound himself, its nature and extent, its relation to the alleged cause, to the probable object desired to be accomplished, and all the circumstances connected with it, before a conclusion should be arrived at. Persons in the public services, it should be remembered, occasionally assist each other in causing mutilations, and in aggravating injuries; so that the moral as well as the physical relations of the subject should be carefully weighed in all cases.

56. I have given the sum of our knowledge as to the means of distinguishing real from feigned disease, and of preventing the consequences of successful deception. I have endeavoured to avoid extraneous matters; and have not introduced amusing instances of simulation, as my limits must be more usefully occupied. The importance of the subject is especially great to the naval and military medical officer; but it is not less so to the civil practitioner; and the success of both in detecting imposture, will mainly depend upon their science, practical knowledge, and ingenuity. With a tolerable store of each, they will seldom be placed in great difficulty, or be obliged to resort to more painful means of detection, than the disease would warrant, were it real.

FEVER. SYN.—Πυρετός (from πυρ, fire); Πυρεξία, Πυρεξίς. Pyrexia, Pyrexis; Febris (from ferbo, or februo, I cleanse). Fièvre, Fr. Fieber, Ger. Fiebre, Ital.

CLASSIF.—1. Class, Febrile Diseases; 1. Order (Cullen).—3. Class, Diseases of Sanguineous Function; 1. Order (Good). III. CLASS, II. ORDER (Author, in Preface).

1. DEFIN.—Painful lassitude, with debility of

the corporeal and mental faculties, alteration of the animal heat and of the secreting functions, accelerated circulation, increased thirst, and abolition of the appetites.

2. The human frame is liable to sudden and powerful impressions from external causes, to the nature or intensity of which it is unaccustomed, and to changes throughout its functions, proceeding from imperfect or impeded actions of some excreting viscus. The derangements thus occasioned, are remarkably varied both in degree and in kind; and they constantly induce further changes, terminating either in restoration to health or in the destruction of the individual. They have been usually named and classed, according to certain distinctions assumed from their chief causes, or from their most prominent features, or from the modes in which their principal characters are grouped. As, however, the various species of change or disorder, thus supervening, insensibly glide into each other; and as some symptoms disappear, and others spring up, from different intensities and combinations of remote causes, from the states of the internal organs at the time when the morbid impression was made, and from the ever-varying influences to which the body is afterwards subjected; so it must follow that distinctions, which are thus based, will become unsafe guides in practice. The manifestations of disease possess no unalterable features; and therefore descriptions of them are to be received with due latitude, and the modes and means of removing them accommodated to individual and ever-varying conditions. From these considerations, it cannot be a matter of surprise, that such diverse opinions have existed as to the nature of those derangements which have generally received the name of fever; and that so much discussion has taken place respecting the differences which exist between them and other disorders, with which, although arising locally, the whole frame more or less sympathises. Nor can we wonder that, owing to the frequent difficulty of distinguishing between fevers and the disorders which thus originate, all differences between them have been denied, and that the former have been actually considered as strictly local diseases. I shall have frequent occasion in the sequel, to notice the grounds on which this opinion is founded.

3. The intimate connection existing between all diseases, which, either at their commencement, or in their course, exhibit febrile symptoms, might have been less a source of error, if the phenomena characterising them had been traced more accurately to their origin, and with a stricter reference to their causes, than they generally have been; and if succeeding and consecutive alterations had been recognised chiefly as effects of the previous changes. If such a course of investigation had been followed, deranged actions, arising almost simultaneously throughout the system, would not so frequently have been mistaken for those which are referrible to a single organ or part; nor would derangements of the former kind have been imputed to such a source. There is no doubt that a certain class of causes will produce both local and general ailment, in different individuals, according to circumstances peculiar to each; or even in the same persons, at different periods, owing to his state, or predisposition, at

the time of their operation. But, still the more remarkable phenomena of these separate diseases proceed in a very different order, and very generally in so marked a manner, as to be easily distinguished by the close observer. The most frequently exciting causes of disorder, viz. mental distress, atmospherical vicissitudes, exposure to cold, moisture, &c., shall, according to the state of the individual at the time, produce an attack of general disease, unaccompanied by predominant affection of any particular organ; and the disorder shall commence and terminate without any complication. In a second individual, a more or less evident determination of the malady, or even inflammation, shall appear in the advanced course of the general disease, or even during convalescence. In a third, the local disorder shall be coëtaneous, and more or less co-ordinate with the general affection, or even outstrip it in violence during its course. And in a fourth person, local disease alone shall be primarily caused; on which, as it increases, and as inflammation becomes more fully developed, symptomatic fever, or the general derangement, shall supervene. These different states of diseased action follow the same cause, according to the disposition, susceptibility, or states of the system at the time. One person, according to this proposition, may have the constitutional derangement complicated with *rheumatic, catarrhal, bilious, nervous, gastric, or dysenteric* affection; the general disorder being attended from some early stage of its course, or from the commencement, by a heightened disease of a particular organ, or structure, and thereby constituting varieties of fever, which have been thus denominated and described by STOLL, DE HAEN, REIL, FRANK, HILDENBRAND, and others, and have occurred in epidemic forms on various occasions. Another person may have the nervous, the gastric, or the dysenteric characters superinduced in the progress of the disease, owing to external causes continuing in, or coming into operation; or to improper treatment: and a third may experience, in consequence of the pre-existing state of a particular organ or texture, an attack of inflammation, from a similar set of causes to those which produce idiopathic fever. If, therefore, the species of disease which arise from one class of causes are thus varied, owing to the predisposition of certain organs, or to the susceptibility of the whole system, their number must necessarily be further increased, and their characters very materially changed, when the additional influences of marshy exhalations, epidemic constitutions, or specific infections and contagions, come into operation. Diseased actions become not only more varied and extended by such additional causes, acting either singly or in conjunction, but also much more complicated and violent.

4. These inferences may be legitimately deduced, from an extensive survey of some of the circumstances connected with acute diseases. Their relation with such derangements as have obtained the appellation febrile, is still more intimate than with those which, strictly local at their commencement, induce consecutively general disorder. It is necessary, however, to the proper consideration of the pathology of fever, that due regard be paid to the nature and extent of its causes, and of modifying or determining in-

fluences, as far as they can be ascertained; and that a strict reference be had to the effects observed to follow the application of both classes of agents, under opposite or varying circumstances. It will also be requisite, while such an inquiry is being prosecuted, that none of the early and intermediate changes be omitted. Such omissions have but too often vitiated our speculations on the nature of disease, and more especially of fever; for, instead of recognising the early changes and states, particularly those which more directly arise from external agents, consecutive and gross effects only have more generally been seized upon, and assigned as the cause of disease. Let it not be supposed that inquiries, such as have just been recommended, are productive of no advantage in practice. The scientific practitioner will consider the most effectual means of preventing, controlling, or removing disordered actions, to be indicated by a most careful scrutiny into their nature and extent, and by a judicious inquiry into early aberrations from the healthy condition. He will view the primary derangements, in the relation they hold with their remote or occasional causes, on the one hand, and with consecutive or ultimate lesions on the other; and will thus trace each individual link of the chain of causation throughout.

5. If it be asked, What has the treatment of fever gained by our speculations as to its nature? I would answer, almost every thing. I will show this in a more demonstrative manner in the sequel, by adducing the opinions which have formerly been held upon the subject, with the practice to which they have led. But, independently of the practical results of the inquiry, there are other solid and not less alluring inducements which will operate on the inquisitive and well-tutored mind. An individual possessing a mind so constituted, feels a laudable zeal in examining into the nature of a class of disorders, which concerns not only the existence of a single individual, but influences also the prosperity of nations; and, who, entertaining even a moderate idea of the responsibility which the exercise of his profession involves, can enter upon its practical discharges, in respect of this class of diseases especially, without feeling some desire of extending his knowledge of their nature, in order that the course he pursues may be both rational and successful?

6. I. GENERAL VIEW OF FEVER. — Fevers are the most prevalent of all diseases, especially in some countries and localities; and their causes frequently cannot be avoided nor counteracted by human foresight or science. They are more especially prevalent among, and injurious to, the human species, as the history of epidemic, pestilential, and other fevers fully prove; and as evinced by those infectious fevers which often occur in camps, and follow the rears of armies during warfare, and which are sometimes much more destructive than the most hard-fought battles. — Epidemic fevers are not, however, confined to the human species; the causes in which they originate, and the influence which promotes their extension, frequently affecting also the lower animals, — a circumstance of importance in our speculations respecting the origin and nature of this very important class of maladies.

7. i. CHARACTERS OF FEVER. — It is impossible

to give a definition of fever altogether applicable to the various forms and states it occasionally exhibits. To convey, therefore, a proper idea of what constitutes *idiopathic fever*, especially, a description instead of a definition of it is necessary; and, for this purpose, those phenomena which are the most constantly present, should be selected: their presence individually, although in various degrees, constituting its essential characters; and enabling the physician, from the manner in which each presents itself, and is associated with subordinate or contingent phenomena, not merely to recognise the different varieties and conditions of fever, but also to distinguish it from diseases intimately related to it. If one, and especially if more, of these constant and essential characters be absent, *idiopathic* or essential fever is not present. An intimate view of its various phenomena can detect comparatively few which exist always in every form of the disease, and in some part of its course. These are — 1st, Spontaneous and painful lassitude; — 2d, Weakness of the corporeal and mental faculties; — 3d, Alterations of the secretions; — 4th, Altered animal heat; — 5th, Quickened circulation; — 6th, Increased thirst; — and abolition of the appetites.

8. *a. Lassitude*, although obviously the result of a morbid impression made upon the nervous system, is generally viewed as spontaneous, the patient often not being able to refer it to a particular cause; and it is usually attended by a painful or irksome sensation in the back and limbs. It is present in every form, especially in some of the stages of fever, and is always one of the earliest and most constant symptoms. It is wanting in many of the diseases which resemble fever; and is manifestly referrible to the depressed state of nervous energy, more particularly as respects the organic nervous system.

9. *b. Weakness of the corporeal and mental Faculties* is, in many respects, a mode of the foregoing; or rather, both are associated effects of the more immediate impression made upon the system by the exciting causes of fever. This debility, as well as the lassitude, often precedes the evolutions of the disease; and always attends it, but in various grades throughout. It is especially evinced in the muscular organs; and less so in the mental faculties, particularly at the commencement. But, although these latter are not much affected as respects some manifestations, others are more evidently weakened. The powers of attention, comparison, &c. are most debilitated, and imagination least so. There are commonly a painful or confused feeling referred to the head, and a peculiar sensation with pain in the loins and limbs; these sensations being the more intense, the severer and more dangerous the disease, and sometimes amounting to an almost entire annihilation of the muscular and cerebral manifestations. These changes never reach above a slight degree in symptomatic fever, or in other diseases, unless when the brain is overwhelmed by effusion of fluid; and then the attendant symptoms and procession of morbid phenomena, are very different.

10. *c. Lesions of the secreting and exhaling Functions* are amongst the earliest, the most constant, and most important phenomena of fever. The *exhalations* from the lungs and skin are evidently the earliest and the most affected; although

the extent of the lesion cannot be readily ascertained and duly appreciated; and it is not improbable that the more energetic causes of fever make their impression on the frame through the medium of the respiratory functions; terrestrial exhalations and infectious emanations floating in the air, and inspired along with it, affecting the nervous influence of the lungs, and associated viscera, and impeding the changes which the blood undergoes during respiration. — Besides these, the salivary, the gastric, the hepatic, the intestinal, and the urinary secretions are more or less altered, as respects either quantity or quality; the alterations being somewhat different in different types, and states of fever. — The early and remarkable lesions of the secreting functions, and the generally imperfect actions of the excreting organs, especially in the early stages, are important, not merely as they form a part of the circle of morbid actions characterising the disease, but, as they especially lead to most of the ulterior changes and complications observed in its advanced course. They evidently depend, at their commencement, upon deficient organic nervous power, occasioning at first imperfect or scanty secretion and excretion; and, at later periods, upon the morbid or vitiated state of the blood, the secretions and excretions then frequently becoming free and copious, but altered from their healthy characters. In symptomatic fevers, the secreting and excreting functions are but slightly disordered, and seldom to the extent of vitiating the circulation.

11. *d. Alterations of Animal Heat*. — The temperature of the body is variously altered in different stages of fever. On the invasion and period of exhaustion, particularly the former, it is often below the natural standard; whilst it is generally above natural, during the period of excitement; this symptom chiefly depending upon the state of vital and nervous energy, upon the changes effected by respiration on the blood, and the resulting condition of vascular action. It is not, however, a mere increase or diminution of heat which is observed, but a peculiar or morbid alteration of it that hardly admits of description. This morbid sensation attending that produced by the change of temperature, and which the physician duly appreciates, varies somewhat in different fevers, is partly also dependent upon suppression of the cutaneous exhalation and the state of the circulating fluids, and is most remarkable in the more dangerous and malignant forms.

12. *e. Quickened Circulation* has been considered by writers as one of the most essential symptoms of fever; and by some as the chief phenomenon; their definition of fever being, increased frequency of the circulation with lesion of the functions. But this definition would embrace equally all the diseases in which quickened circulation occurs. It should be recollected that in some stages, particularly in malignant fevers, acceleration of the circulation is not constantly present; yet it is seldom altogether absent from the commencement. The rapidity of the circulation is, however, often of less importance, than other states of the vascular system, and the condition of the blood itself.

13. *f. Thirst* is seldom wanting in fevers, during all their course, although occasionally absent, particularly in their advanced stages, and in cases

attended by congestion of the vessels of the head. It is observed in other diseases; but it most constantly accompanies fever. — *g.* The appetites also are more or less affected. The appetite for food is diminished or entirely abolished. In rare cases, a craving for food has been observed in an advanced stage of fever, but not throughout its whole course. The appetite for the sex is also abolished until convalescence has commenced, when it reappears, and is sometimes one of the earliest signs of amendment. These symptoms probably depend upon the same cause—upon depressed organic nervous influence, and consequent deficiency of the secretions.

14. ii. GENERAL DESCRIPTION. — The word *Fever* is used in a double sense: it is applied — 1st, to that state of constitutional disturbance, in which the above symptoms are primary, essential, or idiopathic; and, 2dly, to the general disorder consequent upon, or symptomatic of, some local disease. In the latter, the febrile symptoms consist chiefly of increased heat and accelerated circulation; and without these the patient is said to be without fever. But when fever occurs primarily — is a disease *sui generis* — these two symptoms are seldom the most prominent, and are always associated with others, especially those already noticed, which may be much more manifest than they, and which are either altogether wanting in symptomatic fever, or not similarly associated, or only occasionally present. This distinction is necessary, particularly as respects the treatment, and should never be overlooked. Its importance will be more apparent in the sequel. I shall first describe fever as a disease *sui generis*; and next, as a *symptom* of inflammation, or some other disease of a particular organ or tissue.

15. IDIOPATHIC FEVER presents, during its whole progress, characteristic symptoms, not consisting merely of increased frequency of circulation and augmented heat, which are sometimes wanting in certain stages of the disease, but of other morbid phenomena that are equally important, that vary in degree and in modes of association with one another, and that superintend other phenomena thereby giving rise to the different forms and states in which the disease occurs; — it commences with debility and lassitude, which are followed by chills or rigors; it is generally composed of several invasions or exacerbations; it implicates the whole of the vital endowments and faculties, the fluids, and the entire organisation; it is acute and dangerous in its course, with lesion of the circulation, with alteration of the animal heat and of the secretions, and with diminution of vital power; and it is versatile as to its symptoms and type, with efforts at sudden changes or crises.

16. 1st, *Fever begins with lassitude and debility, generally followed by chills or rigors.* — It originates in causes which affect the vital energies of the system, and occasion debility and lassitude as the earliest and most remarkable changes. These are generally attended by an insuperable feeling of fatigue upon the least corporeal or mental exertion by stupidity, loss of nervous and mental energy, by irritability, moroseness, or impatience, and by heaviness of the eyes. Upon these supervene various uneasy sensations; as, anxiety at the præcordia, occasioning frequent full or laboured inspirations; a peculiar and general uneasiness and restlessness;

a feeling of cold, particularly along the spine, and differing from the real or usual sensation; horripilations, involuntary shudderings, and tremors or rigors. The debility giving rise to the unconquerable sense of lassitude and fatigue generally precedes the chills for some indefinite time, and accompanies them or continues after them. Chills or rigors often return and alternate with flushes, and other incipient disturbances, for a variable period.

17. 2d. *Fever is very frequently composed of several invasions or exacerbations*, one paroxysm disposing to others; as in agues and remittents. But even in continued fevers a similar circumstance very often obtains, as evinced by the evening exacerbations, and the aggravation of the symptoms on alternate days. Some writers, and more particularly HILDENBRAND, consider that, as in remittents, wherein a new invasion supervenes before the previous paroxysm had subsided, so in continued fevers, one fit runs into another. — “Continuæ ergo febres, si non omnes, saltem pleræque, præsertim criticæ, è plurimis paroxysmis febrilibus, quorum unus alterum subintrat, composita sunt.”

18. 3d. *Fever is a disease of all the vital endowments, functions and faculties, of the fluids, and of the whole organisation.* — If we trace the progress of fever, from the operation of its causes through successive changes, we shall find that the vital power, which is supreme over the physical properties and functions of our different structures is deeply affected throughout all its subordinate manifestations — as the *sensibilities* of the nervous systems, the *irritability* of involuntary and voluntary muscular fibres, the *organic contractility* of membranous parts. Hence proceed lesions: — (a) *Of the organic functions* — of the respiratory actions and functions, of circulation and of the circulating fluids; of secretion and excretion, of digestion, assimilation, sanguification, and nutrition; of the appetites, both natural and acquired, &c. — (b) *Of the cerebro-spinal and animal faculties* — of the functions of sense and voluntary motion, and of the powers of mind: the expression of the countenance and the attitudes are changed; the senses either perform their parts imperfectly, or the mind takes an insufficient cognisance of their reports; the attention is wavering and quickly fatigued; the intellectual powers and states are languid, feeble, or otherwise disturbed; the judgment is perverted by internal and involuntary impressions and conceptions; and ultimately all the mental endowments become exhausted and disordered, by prolonged wakefulness, or overwhelmed by a continued sopor. — (c) *Of the fluids and whole organisation*: — The fluids and soft solids undergo changes in their appearances, form, and properties. The blood is evidently altered in various ways at different periods of the disease. Its serum is often at first in considerable quantity, and its crassamentum loose; but afterwards the latter generally becomes more firm or cupped; and ultimately again loose, or imperfectly separated from the serum. In many cases it is still more remarkably altered, as shown in the article BLOOD (§ 78 et seq.) both in colour and consistence. The secretions, which are at first chiefly diminished in quantity, ultimately are changed in quality. They become more offensive, of a darker colour,

and more irritating and septic to the tissues with which they come in contact.—The *soft solids* are to a certain extent affected, owing to the changes previously induced in the powers of life and in the circulating fluids, as respects the *form, appearance, and properties* of all their parts. The cutaneous surface loses its lively tint, is changed in colour, or assumes a dirty, dusky, or earthy hue. The integuments become loose or turgid, harsh or burning; the muscles and cellular parts suffer a diminution of their consistence, and subsequently of their bulk; and the *physical*, as well as the *vital, properties* of all the tissues, especially their cohesion and elasticity, are very much impaired. Ultimately, the soft solids present a more flabby, dusky, brownish, or livid hue, and are softer and more lacerable than natural. Thus the eyes, lips, mouth, the countenance and whole physiognomy, the skin, the flesh, the habit of body, and the postures of the patient, exhibit the universality of disease. From these facts, *fever may be defined pathologically*, or with reference to the vital and organic changes, to be an *acute affection of all the functions, and of all the fluids and soft solids of the frame*.

19. 4th. *Fever proceeds with lesions of the circulation, of the secretions, and of the animal temperature; and with depression of vital power.*—The pulse is generally accelerated in some one stage or other. When it rises not above, or sinks below, the natural frequency, the cause may either be congestion of the vessels of the head, or the morbid state of the blood, or the influence of the supine posture on certain constitutions. In these cases the pulse often becomes much more frequent when the trunk of the body is raised to nearly an erect position, or even when the head is elevated (§ 12.). The *secretions* I have already stated (§ 18.) to be early and remarkably changed. The extent and consequences of the alteration will be especially considered hereafter. The *temperature* is altered during some period in all fevers. Instances, however, occur, in which increased temperature does not supervene on the cold stage: there are also cases in which coldness soon follows upon more or less of heat; and others in which the alteration either way is very slight. Still some change may be felt, generally in degree, but also in respect of other sensations connected with it, excited in the patient and in the observer. In some cases, especially early in the disease, the patient's feelings may be those of cold, whilst the surface is actually warmer than natural. The *depression of vital power* is evinced from the commencement, in all the functions; and does not the less exist, because vascular excitement or reaction becomes great or excessive during a part of the disease. Although vascular action is increased for a time in most fevers, yet vital power or resistance is lowered nevertheless, especially in other systems and organs, and is afterwards further exhausted in proportion as vascular action has run high, and it ultimately becomes remarkably lowered with the contamination of the fluids and of the soft solids; impaired power augmenting the changes of these, which, in their turn, increase the depression, and often even accelerate the extinction of life.

20. 5th. *Fever is acute and dangerous in its course.*—A single attack of fever scarcely ever continues beyond thirty days. When it is ob-

served to remain longer, it may generally be considered symptomatic of superinduced inflammation, or of altered structure, or a relapse. Intermittents, however, are often of much longer duration, but each paroxysm may be considered as a distinct attack. Remittents, also, sometimes continue longer; but seldom or never, unless associated with visceral disease, which prolongs the febrile action, or converts it into a symptomatic fever, retaining more or less of the remittent, or passing into the continued type. The *danger* of fever results from its nature, and varies with its type, form, and violence; for it is liable to sudden vicissitudes in its progress, and is prone to produce changes of structure having a fatal tendency. Even the most mild form of fever may suddenly change its character from internal or external causes, or from abortive or irregular efforts at a crisis, or from an injudicious regimen or treatment, and put on a most dangerous form; or, owing to predisposition or pre-existing disease of a part, give rise to fatal disorganisation in some important or vital organ.

21. 6th. *Fever is mutable in its characters.*—It is but one disease, or *genus*, comprising several species, and subordinate varieties—numerous and ever-varying forms and states resulting from the nature, the combination, and the intensity of the causes, acting upon peculiarities of constitution and predisposition. Hence we cannot be surprised to find fever *mutable* in many of its characteristic phenomena—to observe one species or variety closely approximate others—and even to meet with instances of one type, or form, suddenly or unexpectedly changing into another, in some period of its progress. Thus it is not unusual to see a simple tertian change to a quotidian or double tertian; or an intermittent pass into a remittent, or this latter into a continued form. Occasionally the disease alters from mild to severe, or from nervous to malignant. It sometimes is simple through a great part of its course, without any one organ suffering a predominating disturbance, and yet it suddenly becomes very dangerously complicated, and thereby assumes very different features.

22. 7th. *Fever evinces a tendency to sudden changes or crises*, owing to the conservative influence of vital resistance and reaction. These are generally of a salutary nature, when not rendered abortive by some external or internal cause, by the injudicious interference of art, or by pre-existent lesions of an important viscus. When they are fully evolved under the conservative influence of life, so as to lead to the salutary termination of the disease, they have usually received the name of *CRISES*. They are observed not only in continued fevers, but still more remarkably in the paroxysms of an ague, each of which, when once commenced, will proceed until the powers of life terminate it by a critical change. Idiopathic fevers have frequently been denominated *critical*, as distinguishing them from symptomatic fevers, which less frequently experience this mode of termination, and generally in a less decisive manner. When salutary processes supervene, and are developed so as to terminate the disease, a more rapid and perfect return to health is experienced, than under other circumstances. It would seem that the evacuations by which favourable changes are brought about, are in

some respects a depuratory effort of nature, more especially as those evacuations generally occur through the medium of organs which eliminate hurtful materials from the circulating fluid. Hence, one of the safest modes of practice is that which keeps these salutary processes in view, avoiding whatever may prevent them, and promoting their evolution; attending at the same time to the preservation of the powers of life, and warding off danger from weakened, over-excited, or oppressed organs.

23. When we take into consideration the conservative influence of the vital energy, the salutary changes brought about by it, and the circumstance that every method of cure, or every agent, cannot act in a similar manner in all cases—and that, even during the most injudicious treatment, certain of the agents are calculated to meet the exigencies of some cases, either in supporting the powers of life, or in favouring or determining some critical evacuation—the reason will readily appear, why recovery often takes place in fever from the most opposite means, or when left entirely to nature; and we shall easily understand wherefore all do not die who are improperly treated, and how nature often not only overcomes the disease, but also the effects of injurious agents prescribed for it. Of the means which are employed in the treatment of fevers, there are not any which become more dangerous from inappropriate use, than the extreme measures frequently resorted to—namely, large depletions and active stimulants. The former may destroy, in a few hours, cases which nature or opposite measures might have preserved, and the latter may over-excite, and inflame to disorganisation, viscera which require to be unloaded, or to have their actions moderated.

24. It not infrequently, however, happens that the critical efforts are imperfect owing to exhausted vital power, or insufficient from the nature and severity of the disease, or misdirected or irregularly exerted in consequence of some controlling or determining influence; and hence they become sources of increased disorder, or superinduce structural change. Such results are sometimes favoured by over-active, inefficient, or inappropriate means of cure; and very often by organic lesions having taken place in so great a degree, and so early in the disease, that the salutary efforts attempted cannot subdue them, but merely tend in some instances to their aggravation and danger.

25. The event in fevers is directly produced by critical changes, and indirectly by the assistance of art: it is favourable, if the powers of life remain unsubdued and act without obstruction; it is unfavourable, if they languish or are overwhelmed. So much are we indebted to the conservative efforts of life exerted throughout the frame in the cure of fevers, that more is often to be ascribed to this source than to the interference of art; and I may add in the words of Professor HILDEBRAND, “Inde enim pendet, quod miseri ac inepti medici famam, quam buccis inflatis non accipere, sed verecundi naturæ magistræ reddere debent, in febribus sanandis sibi conficiunt. Inde pendet quod omnis sectæ medici, ac oppositarum mædendi rationum adsectæ, de felici eventu in febrium tractatione gloriantur. Inde evenit pendet, quod quævis theoriarum ad febres curandas applicata,

sanatorium agrorum practica exempla offerre valeat.” (Vol. i. p. 53.)

26. SYMPTOMATIC FEVER. — Fever may be a concomitant or an effect of another disease, which would still remain were it possible to remove the attendant fever; but which being removed, the concomitant fever would cease. In as far as it consists of accelerated circulation, fever may be associated with the majority of diseases; but it is still merely a single symptom, wherefore other phenomena should be present before even symptomatic fever ought to be said to exist. Whatever irritates or stimulates the circulating system to a stronger or more frequent action, or inflames a particular part, is productive of symptomatic fever. Its cause exists within the frame, and more rarely it acts from without; as irritation or inflammation of particular tissues; the presence of foreign bodies, or of calculi, worms, or hurtful ingesta; the absorption of hurtful or acrid matters, or of contaminating secretions; surgical operations, external injuries, and violent exertion. Fever proceeding from these sources has been termed *inflammatory, irritative, fever, from irritation, fever of the vascular system, symptomatic inflammatory fever, symptomatic fever, chronic fever, hectic fever*, according to the peculiar irritation, or local disease, on which it attends.

27. Fever is associated with other diseases in a twofold manner:—1st. *Essentially*, forming what are called *febrile diseases or symptomatic fevers* strictly speaking; as in *tabes purulenta*, in which it is merely a symptom, but one which is uniformly present. 2d. *Accidentally or contingently*, not naturally and constantly, but merely from the association of some occasional disturbance or complication, as in amenorrhœa, chlorosis, dropsy, rheumatism, &c.; or as a consequence of treatment. In symptomatic fevers, the constitutional affection is neither so severe, nor so generally and equally extended to all the functions, nor so entirely implicates the fluids and soft solids, as in idiopathic fever. Hence they are more readily traced to their origin—to the irritation in which they arise. The functions which chiefly manifest disturbance in their progress are those of circulation and secretion—the latter often very slightly. Others are also occasionally disturbed, as those of the skin and of the nervous system, but generally in an indirect and slight manner. Consequently the chief characters of symptomatic fevers are quickened pulse, heat of skin, disorder of its transpiration, and thirst. The excretions, muscular power, and the faculties of mind, are but little altered. The pulse retains greater tone and sharpness, and the general surface more animation than in idiopathic fever. The external physiognomy, the posture, the extreme prostration of muscular power, the profound alterations of the vital endowments of the fluids and of the organisation itself, characterising the latter, are either altogether absent, or present in a very slight degree merely, unless when morbid matters are conveyed into the circulation during the course of certain symptomatic fevers, and thereby vitiate both it and the soft solids, disordering also the different secretions and excretions. Such occurrences sometimes take place, and have fallen repeatedly under my observation, particularly when inflammation attacks the internal surface of

vessels, or when purulent or sanious matters are taken up and conveyed into the blood, as in certain puerperal and other diseases. The vitiation of the circulation thus produced, and the effects upon the nervous system and other structures, are such as to give rise to a state of disease altogether similar to some of the worst forms of idiopathic fever.

28. The *duration* of symptomatic fevers depends entirely upon the nature of their causes, and the permanence of the original affection from which they proceed. Sometimes they are short, or even ephemeral, the irritation which occasioned them being removed by the actions which it induced: in other cases, their continuance is often very long. But the character of the phenomena experiences but little alteration, and they seldom undergo much change in their type. They are not, however, devoid of efforts at a critical evacuation; but these are more frequently inefficient and abortive, than in idiopathic fevers, owing more to their being insufficient to remove the primary malady than to defective vital energy. They are, however, occasionally relieved or even removed by spontaneous hæmorrhages, vomitings, diarrhœa, copious perspirations, and critical secretions of urine. Unfavourable terminations frequently also take place owing to congestions, obstructions, or disorganisations in some vital organ, arresting its functions. The *treatment* of symptomatic fevers is necessarily directed less to the particular phenomena they present, and more to their origin, than that of idiopathic fever. It is generally founded upon the intention to remove the cause; and, when this cannot be accomplished, to render it less injurious.

29. II. THE DIAGNOSIS OF FEVER.—From the description which has been given of the pathognomonic symptoms of *idiopathic fever*, and of the general characters of *symptomatic fevers*, the differences between both, and between the former and other diseases, will be evident. The distinctions just stated between idiopathic and symptomatic fever equally exist between the former and *inflammation*; this latter being one of the chief causes of symptomatic fever. Inflammation, in its primary and phlegmonoid form, attacks not only a single tissue or part, but also in a manner indicating its locality; the resulting constitutional affection differing in its mode of supervention and in its characters (§ 7. *et seq.*), from fever, as above described. It should, however, be recollected that inflammation frequently supervenes in parts or organs at some period of the course of idiopathic fever, or even at its commencement; and indeed the fevers of some seasons, or epidemics, are very generally thus *complicated*. In these cases, however, the inflammation does not present the characters it assumes in the previously healthy frame, but those it puts on when occurring in a very unhealthy or cachectic habit of body; it being engrafted, when supervening in the course of idiopathic fever, upon a morbid condition of the constitution as respects the vital endowments, the fluids, and the soft solids. Hence, when once excited, particularly in membranous or cellular parts, inflammation rapidly extends or passes into disorganisation, owing to the remaining tone of the vessels, and to the already reduced vital resistance being rapidly exhausted by the generally as well as locally increased vascular action. It presents, in such circumstances, many of the cha-

acters possessed by erysipelatous inflammation, and very nearly approximates to it; but is frequently still more dangerous, insidious, and rapid in its progress to fatal disorganisation.

30. Fever differs from diseases usually denominated *cachectic*, inasmuch as in them the external habit and appearance of the soft solids are principally affected, and the powers of life much less than in fever. They supervene gradually and imperceptibly, and proceed slowly, without much, or even any, acceleration of pulse, or increase of temperature. They present not the complete prostration of muscular power, the versatility of character, the mutability or disposition to change, and the efforts at vital reaction, which distinguish fever; and nature does little towards removing them, whilst art effects much.

31. Fever differs from disorders termed *nervous*, in the latter being altogether referrible to the cerebro-spinal nervous system, or parts intimately connected with it, whilst other systems and organs are either unaffected or not proportionately affected. They present but little change of the circulation, or of animal heat, or of the secretions, or of the intrinsic condition of muscular power, or of the soft solids in general. They are, moreover, generally chronic; they follow no determinate course, are cured with difficulty, and yet are seldom removed by the unaided efforts of nature. Other diseases, as those which are local or attended with increased discharges, are at once distinguishable from fevers by their essential or pathognomonic symptoms.

32. III. OF THE GENERAL COURSE OF FEVER.—Fever commonly runs a determinate course, unless death occur so early as to prevent it. In order to give precision to our knowledge of the usual progress of the disease, and to enable us to employ the means of cure with a stricter reference to existing pathological conditions, several stages or periods have usually been pointed out, according to the changes observed in its course. Writers have differed materially as to the number of stages into which fever should be divided, and as to the terms by which they should be designated. As respects eruptive fevers, no difficulty need exist as to either. I shall pursue, therefore, that arrangement which my observation of the progress of fever has convinced me to be correct, and which is applicable to continued and periodic fevers equally with those which are eruptive.—Fever consists—1st. Of the *formative* or *precursory* stage;—2d. Of the period of *invasion*;—3d. Of *excitement* or *reaction*, comprising (a) *incremental* excitement, and (b) *stationary* excitement;—4th. Of the stage of *crises*;—5th. Of *decrement*, or decline;—and, 6th. Of the period of *convalescence*.

33. A. *The Formative or Precursory Stage*; *Stadium Opportunitatis*, HILDENBRAND; *Stadium Prodromorum*, REICHE, HELLING, and RICHTER; *The latent Period*, of Dr. MARSH; *The Stage of Incubation*, of French writers; *The dormant Period*, of English authors.—Although the precursory symptoms of fever have been fully enumerated by CELSUS (*De Med. lib. ii. cap. 2.*), they were overlooked by writers until the middle of the last century, when TISSOT, REICHE, and HELLING, directed attention to them. FORDYCE, and other more recent authors on fever in this country, have left them entirely unnoticed. In my papers on fever published between 1819

and 1828, and in my lectures delivered from 1823 to 1827, particular notice was directed to the subject, and these symptoms were described as constituting a most important stage of the disease, inasmuch as in it the nature of fever would be most advantageously studied, and either its subsequent course remarkably meliorated, or its further progress prevented, by appropriate and energetic treatment. (*Lond. Med. Repos.* vol. xviii. p. 238.; and other *Refer. in Bibliog.*)

34. The phenomena described above, as characteristic of idiopathic fever, never proceed immediately from the remote causes. The impression made by them occasions a succession of changes before those which really constitute fever supervene. These early changes, being productive of those which constitute the developed disease, may aptly be called *formative*; and the symptoms by which they are indicated, *precursory*. The exciting causes of fever seem to act primarily upon the nervous system of organic life, thereby producing changes in the vital manifestations of the frame, which gradually increase until they arrive at a certain pitch, and terminate in one of the modes hereafter to be noticed. The more intense the exciting causes, the predisposition being equal, the shorter will be the duration of this period, and the sooner will the lesions constituting fever be brought about (§ 15.).—(a) The earliest effect which is made manifest after exposure to the more energetic causes of fever, as infectious effluvia or noxious exhalations, is a feeling of constriction or oppression in the chest or at the præcordia, attended by frequent sighing, gaping, forced and lengthened inspirations, and by a sense of uneasy depression, or nausea, evincing the morbid impression made upon the nervous system through the respiratory organs. The pulse is weak, slow, irregular, sometimes remittent or reduplicating, and readily accelerated by slight exertion.—(b) The natural and acquired appetites and desires are diminished; nausea is readily excited by food; and the bowels are either costive or easily acted upon by purgatives; *Venus silet*, and all the *organic junctions* are impaired.—(c) The patient feels debilitated and fatigued; complains of headach, vertigo, or confusion of ideas; is morose, low-spirited, sluggish, indolent, or incapable of exertion and of directing his attention long to any object; he readily perspires, and his breathing becomes short and quick, on the least exertion; his sleep is unsound and unrefreshing, and he awakens with a sense of lassitude or with pains in his back and limbs,—in short, all the *cerebro-spinal functions* are weakened or disordered.—(d) The external expression and appearance are somewhat altered. The countenance and skin are unusually pale, sallow, or unhealthy; more rarely red. The eyes are languid, and deficient in brilliancy. The breath is fetid or cool; and the tongue often loaded. The urine is sometimes pale and copious; and the cutaneous surface dry, cool, and harsh. These symptoms vary in severity, and often are so slight as to escape particular attention. They frequently are insufficient to induce the patient to confine himself.—(e) The *duration* of this stage is various in different fevers—from twenty-four hours, as in plague and some cases of typhus, to several weeks, as in ague; but it is generally from three

to fourteen days. The severer and the shorter this period is, the more acute and the more rapid will be the subsequent progress of the disease, and *vice versâ*: there are, however, exceptions to this. Fever may be cut short in this stage by active and judicious means; but not afterwards, unless occasionally in slight cases.—(f) The *pathological conditions* characterising this stage, are, depression of vital power throughout the frame, with slight internal congestion, particularly of the lungs, liver, &c.; with imperfect change of the blood in the lungs, and with diminished secretion and excretion.

35. *B. Stage of Invasion; Principium vel Initium Febris*, Auct. var.—(a) *The cold stage*, of writers—is attended by debility, lassitude, painful uneasiness, or sinking at the epigastrium, a sensation resembling cold running down the back, with formication or chills extending over the limbs and general surface. The pulse is constricted, small, weak, or accelerated; the respiration is slow, irregular, or suspirious, and attended by anxiety at the præcordia, and occasionally by a slight dry cough. On these supervene gaping, sighing, pandiculation; a sense of weight, pain, or constriction in the head; giddiness, moroseness, depression of spirits, and disorder of the senses; lividity of the lips and nails; pallor of the skin; the cutis anserina, and shuddering, rigors, or shiverings, followed by or alternating with irregular flushes. After the rigors cease, a sense of chilliness often continues for some time, although the skin has become hot. These symptoms present various grades and modifications in the different types of fever: in some the feeling of cold is actually attended by reduction of the temperature; and in others the heat is not materially, if at all, diminished, or it is even increased. The former is most commonly seen in the cold stage of periodic fevers, the latter in the invasion of continued fevers. In all, however, the cutaneous transpiration is altogether arrested, and the skin is harsh and dry. The pulmonary exhalation is also diminished, and the breath is cold. Copious discharges of pale urine often take place, evidently arising out of the arrest of the exhalation from the skin and lungs. Loss of the appetites, costiveness, thirst, and occasionally sickness and vomiting, are likewise present.—(b) *The duration* of this period may be very short; or it may be for many hours, alternating with slight flushes. The shorter and more intense it is, and the severer the rigors, the shorter and severer will be the consequent vascular reaction, and the more nearly approaching the inflammatory type; and the longer its duration, the more prolonged will be the fever. The imperfect evolution of this stage, or its slight occurrence, particularly when it is not attended by rigors, very generally indicates a severe malignant or typhoid state of disease. In some of the most dangerous cases of fever, I have seen this stage so slight, as to be confounded with the preceding one. This period having supervened, the disease cannot readily be cut short by bloodletting, emetics, &c.; although in the slighter cases, and more inflammatory type, these means have succeeded in some instances.—(c) *The pathological states* of the first period are increased in this, particularly the general depression of vital endowment; the impeded functions of the lungs,

liver, &c.; the interrupted exhalation and secretion, excepting the urinary secretion; and the imperfect depuration and arterialisation of the blood. But the lowered vital powers become more centralised; and the congestion of the large vessels, especially those of the thoracic and abdominal viscera, greater, — conditions which terminate themselves, by inducing rigors, shivering, vomiting, and reaction of the vascular system, with the subordinate phenomena of the next stage.

36. *C. Period of Excitement.* — *a. Incremental excitement or reaction — incrementum vel augmentum morbi.* — (*a*) This stage commences with the disappearance of certain of the foregoing signs, with the increase of those that remain, and with the supervention of others. Fever in its more literal sense now begins, and manifests its specific form. The gaping, pandiculation, formation, and rigors disappear; and the stricture and collapse of the countenance and general surface are followed by increased warmth and turgescence. The chilliness, however, continues for a short time. Pulmonary transpiration returns in some degree; respiration becomes full, frequent, and sometimes laboured, and the breath hot. The urine is now diminished, high-coloured, limpid and clear, and its discharge is often attended by scalding. The muscular debility, feeling of fatigue or lassitude, the pains in the head, loins, and limbs, the thirst, and the anxiety at the præcordia, are all increased. The countenance becomes turgid; the eyes shining, but with an expression of languor; the cheeks flushed, and the cutaneous surface hot, burning, and turgescient. The appetites are now entirely abolished; the tongue is loaded or furred, or both; the pulse is free, full, and accelerated; often strong, and vibrating in the neck; but varies remarkably in tone with the particular variety of the disease. There are also a sense of weight, fulness, and aching of the head, with giddiness, confusion of ideas, and sometimes with mental indifference, which short and disturbed slumbers seem to aggravate; a morbid susceptibility or disorder of the senses; and occasionally moroseness, restlessness, or jactitation. These symptoms generally increase, often presenting in the continued type slight remissions in the morning, with exacerbations in the afternoon and evening, and which are most severe on alternate days; and, during the progress of this stage, delirium often supervenes, especially when it reaches its height. — (*b*) The *duration* of incremental reaction or excitement varies with the type and form of the disease — from an hour or two, as in ague, to two or three days, as in continued fevers. It is generally shortest in the most severe and violent attacks; but it never extends beyond seven days. — (*c*) It consists, *pathologically*, of reaction of the vital powers, expressed chiefly in the vascular system, frequently with a preponderance or determination towards particular organs — of the efforts of life to overcome the more immediate effects of the exciting causes, especially the internal congestions, and the superinduced changes in the blood.

37. During this stage, *determination* to particular organs or textures frequently occurs, and thus the fever becomes *complicated*, or resembles idiopathic *inflammation* the more closely, the less severely the vital power and the circulating fluids

are impaired or vitiated. Such determinations or consecutive inflammations are observed principally in the *encephalon*, *spinal chord*, *lungs*, *liver*, *stomach*, and *bowels*; they are caused chiefly by the predisposition, previous diseases, and existing states, of these viscera; and by climate, season, habits, and occupations, and the circumstances of the individual; whatever disorders, irritates, weakens, or causes habitual determination, or increased momentum of the circulation to either of these organs, thus complicating the fever. Hence the *cerebral complication* is most common in the studious; the *gastric* and *hepatic*, in those addicted to the pleasures of the table or to intemperance, and in hot climates, or during warm seasons; the *pulmonary*, in cold countries and seasons, and in persons much exposed to the open air; and the *intestinal* or *dysenteric*, in the ill-fed, in persons using unwholesome water or living upon innutritious and watery food, and in low and moist situations. The *prevailing epidemic* constitution has also a most powerful influence; the complications, as well as the particular form and type, of fever, depending upon it, and the nature of the exciting, concurring, and determining causes.

38. *β. Stationary reaction — stadium ectionis* of the humoralists — consists of the persistence of the above symptoms, with slight modifications and frequently with increased affection of particular organs. — (*a*) During its progress, restlessness continues, with watchfulness; delirium is often constant, or appears for the first time; nervous power is gradually and almost imperceptibly exhausted; the pulse generally loses tone, and becomes more accelerated; the tongue is deeply furred and loaded, and often also parched, and mucous sordes collect about the teeth. Respiration is quick, or moaning, and the breath is foul, heavy, offensive, sickly, and loaded with vapour; the urine is still scanty, high-coloured, and clear; the bowels are either costive or irregular, and the stools morbid and offensive; the countenance becomes pale, heavy, collapsed, and of a sallow or unhealthy hue — sometimes muddy or lurid; the eyes are suffused, watery, heavy, and occasionally injected; the skin continues hot, pungent, or burning, and it afterwards either evinces a disposition to transpiration, or becomes damp and clammy; or it is the seat of petechiæ, or of eruptions, which, in the exanthematous fevers, appear at an early part of this stage; the prostration of muscular power is increased, and is often so great that the patient cannot retain his position on one side, but falls into the supine posture; adipose matter is subsequently absorbed, and the body lives upon itself; and, if the patient be not delirious, he complains of severe pains, or of a bruised sensation, or of soreness in his limbs, back, and loins, with confusion, vertigo, or pain in his head.

39. (*b*) The symptoms vary remarkably in this stage with the type and form the fever assumes — with the complications above alluded to — with those which may supervene during the advanced progress of this period — with the more latent changes in the mucous surfaces, or in parenchymatous structures — and with various influences and circumstances occurring during the disease. In some varieties of the continued type of fever, the whole of this period proceeds with little or no

evening exacerbation, whilst, in others, exacerbations are very manifest; but this depends much upon the prevailing epidemic constitution. In general, fever caused by infection, and complicated with serious visceral disease, or characterised by severe affection of the fluids and soft solids, is strictly continued; whilst that produced by terrestrial emanations assumes somewhat of the remittent form, although presenting much of the continued type.—(c) The *duration* of this state of vascular reaction is shortest in agues, in which it does not exceed a very few hours; and, in continued fevers, it is brief in proportion to the severity of the disease. It rarely, even in the more protracted cases, exceeds fourteen days.—(d) The *pathological states* of the early part of this stage continue in great measure in this part of it; but vascular action exceeds vital power, which is gradually lowered; and the circulating and secreted fluids and the solids themselves become vitiated as already stated, and as will be more particularly shown in the sequel.

40. *D. The period of Crisis — Stadium Criseos — Judicium Febris.*—Crisis in fevers is a sudden change taking place at a particular period of the disease, and terminating it. A crisis is brought about chiefly by the efforts of nature, or, in other words, by the febrile action itself inducing changes in the functions and organs, productive of a salutary effect. Although it often takes place by the unaided efforts of life, it is frequently assisted by art, and should not therefore be preferred before art judiciously employed. The *critical days* are the 2d, 3d, 4th, and 5th (quotidian period); the 7th, 9th, and 11th (the tertian period); the 14th, 17th, and 20th (the quartan period). After the 20th, crises are obscure, and seldom occur till the 27th or 28th. Salutary changes are observed chiefly on the above, unfavourable changes on the intervening days; but death may happen on any day. A very cold climate or season, or either extreme of temperature, the impure air of an hospital, the continued operation of the causes, the complications, great vitiation of the fluids and solids, an active treatment, interfere with, retard, or prevent crises. If the exacerbations be well marked, and vital energy not very much reduced, a favourable crisis may be more confidently expected. Crises are sometimes *indecisive*, or consist of several abortive attempts before the end is attained, especially when the powers of life are much lowered. When several critical efforts are required, each succeeding one renders the task more easy for the next, until the disease is gradually subdued. (See *CRISIS*, and *Critical Evacuations*.)

41. *E. Period of Decline — Decrementum — Declinatio.*—Sometimes the decline is prompt and rapid, especially after a marked crisis (see art. *CRISIS*); at other times it is gradual and slow, particularly when only slight and imperfect crises have occurred, or when the disease terminates in resolution without any very manifest critical evacuation. In the former case, the decline passes quickly into convalescence; in the latter, this stage is often characterised by slight exacerbations, called by some writers posthumous crises, which are apt to be misunderstood. In the fevers of this country, which frequently decline gradually, or in the second of these modes, the symptoms indicative of vital disturbance ge-

nerally subside in the order in which they appeared. Organic nervous influence and the dependent functions are the first to be restored; the respiratory, secreting, and excreting actions become natural; the perspiration more general, free, and, if it have previously been offensive, clammy, or partial, more natural and genial; the tongue begins to clean on the sides and point, and is more moistened by the commencing return of the secretions poured into the mouth; coma and delirium subside; and the patient regains his power over the alvine excretions, if it has been lost; the sensorial faculties and sleep reappear, and the latter becomes more refreshing; the locomotive powers are freer and more energetic, the patient being enabled to turn upon his side, the sense of soreness and lassitude being diminished; the appetites and desires return, and the excretions are gradually re-established. The action of the heart is the last to subside to its natural frequency, and generally continues long afterwards to be readily excited by slight stimuli. The urine is abundant, and deposits a copious sediment; the bowels become free, the motions consistent and feculent, and the skin gradually assumes a clear and healthy appearance; but emaciation increases rapidly, or now is more apparent; absorption, more especially of the less animalised and less highly organised parts or molecules, proceeding rapidly as soon as vascular reaction subsides.

42. *F. Convalescence — Stadium Refectionis — Convalescentia.*—I agree with RICHTER and HILDENBRAND in considering this as a stage of fever. The propriety of this view is obvious, especially as regards the future health of the patient. It is, however, altogether distinct from the malady, inasmuch as it does not present any of the constituent phenomena, which still continued to exist in the stage of decline, but merely those of debility consequent upon acute disease. During its early progress, the bulk of the body still continues to diminish, or does not increase until it is far advanced; all the symptoms entirely disappear; the appetites, desires, digestive functions, the secretions and excretions, are re-established, but are apt to be disordered, and therefore require supervision; the cuticle and sometimes the nails are exfoliated, and the hair falls out. Irritability and sensibility often are increased; and tinnitus aurium is sometimes troublesome; but these subside as health is restored.—*Relapses* are apt to occur in this period, especially from premature exposure or indulgences, or from disorder of the digestive organs; but they more rarely follow when fever arises from infection or from a specific contagion, though other diseases may be thereby occasioned.

43. *IV. OF THE TYPES AND FORMS OF FEVER.*—i. These are determined by the following *circumstances*:—*a.* By the *previous health*, the temperament, and habit of body, and vital energy of the patient;—*b.* By the state of the vascular system, particularly as to the existence of fullness or deficiency of blood;—*c.* By the *specific kind of miasm or cause* exciting fever;—*d.* By the prevailing epidemic constitution;—*e.* By other causes, predisposing, exciting, concurring, and determining; and by the intensity of their action;—*f.* By the *external and internal — the physical and moral — influences*, to which the patient is subjected, from the period at which

the morbid impression was made upon the frame; — *g.* By the *internal congestions, determinations, or inflammations* superinduced in its early course; — *h.* By the *intensity of the morbid impression* made upon the vital endowments, especially of the organic and cerebro-spinal nervous systems; — *i.* By the degree to which vital power is suppressed or lowered throughout the frame; — *k.* By *vitiating of the circulating fluids* and soft solids; — and, *l.* By the treatment and regimen during the commencement and early progress of the fever. These circumstances both determine the particular type, the form, and the complications of fever, and change one type or form into another.

44. ii. The *Types and Forms*, which usually present themselves as the result of the remote and efficient causes, and as influenced by the above circumstances, are —

A. The *INTERMITTENT*, — *a.* of a *quotidian*, — *b.* of a *tertian*, — *c.* of a *quartan*, type; either of which may be — *a.* *simple*, — *β.* *double or reduplicating, or irregular*, — and, *γ.* *complicated* — 1st, with abdominal visceral disease, — 2dly, with cerebro-spinal affection, — 3dly, with alterations of the fluids and soft solids, — and, 4thly, with visceral lesion and with change of the fluids and solids — the pernicious or malignant agues of some parts, particularly in warm climates.

B. The *REMITTENT*: — *a.* *Simple*, — *b.* *bilious, c. inflammatory*, — *d.* *bilio-inflammatory*, — *e.* *adynamic or malignant*, — *f.* *gastro-adynamic*, — *g.* *typho-adynamic*, or associated with severe cerebral affection, — *h.* *complicated* — *a.* with pulmonary disease — *β.* with disease of the spleen, — *γ.* with disease of the large bowels, — *i.* *slight and chronic*.

C. The *CONTINUED*: — *a.* *Ardent fever*, — *a.* *diary fever*, — *β.* *bilious, inflammatory fever*. — *b.* *Synchoid*, — *a.* *simple*, — *β.* *complicated*, with predominant affection — 1st, of the stomach and liver — *mild gastric fever*, of authors, — 2dly, of the intestinal mucous surface — *mucous fever*, — 3dly, of the cerebro-spinal system — *nervous fever*. — *c.* *Typhoid or Adynamic fever*, — *a.* *simple*, — *β.* *complicated* with predominant affection — 1st, of the gastro-intestinal mucous surface — *adynamic*, of French writers, — 2dly, of the lungs and bronchi, — 3dly, of the cerebro-spinal nervous system — *ataxic*, of PINEL, — 4thly, of the mucous surfaces and brain — *typhus*, of writers, — 5thly, of these surfaces, brain and skin, with efflorescence or eruption — *exanthematic typhus* (HILDENBRAND), or with petechiæ — *petechial typhus*, — 6thly, of the vascular system and circulating fluids — *malignant or putrid fever*.

D. *PESTILENTIAL FEVERS*: — *a.* Evincing predominant affection of the fluids and solids, and of the gastro-intestinal mucous surface, with yellow skin — *epidemic yellow fever*; — *b.* of the fluids and solids, and of the lymphatic glands — *plague*; — *c.* of the vascular system and blood, and of the lungs and gastro-intestinal mucous surface, with spasms — *pestilential cholera*.

E. *EXANTHEMATOUS FEVERS*: — *a.* *Scarlet fever*, — *a.* *mild or benign*, — *β.* *synchoid scarlatina*, — (*a*) *simple*, — (*b*) *complicated*; — *γ.* *adynamic scarlatina* — (*a*) *simple* — (*b*) *complicated*, — the complications in both varieties being with inflammation of the throat, or of the gastro-intestinal mucous surface, or of the membranes of the brain, or of the respiratory surfaces, or with any two or three of them; — *b.* *Measles*, — *a.* *mild*, — *β.* *sy-*

nchoid measles, — (*a*) *simple* — (*b*) *complicated* — *γ.* *adynamic measles* — (*a*) *simple* — (*b*) *complicated* — the complications being nearly as above; — *c.* *Small-pox*, — *a.* *mild*, — *β.* *synchoal* — (*a*) *simple* — (*b*) *complicated*, — *β.* *adynamic or confluent* — (*a*) *simple* — (*b*) *complicated* — the complications being nearly as above; — *d.* *Erysipelas* may be similarly divided.

F. *PUERPERAL FEVERS*: — *a.* *Inflammatory*, — *a.* *inflammation of the uterus* — *β.* *of the ovaria and tubes* — *γ.* *of the peritoneum* — *δ.* *of any two or all of them*; — *b.* *Synchoid puerperal fever*, — *a.* *complicated* with inflammation of the peritoneum — *β.* *with inflammation of the uterine veins, &c.* — *γ.* *with inflammation of the uterus and appendages*; — *c.* *Malignant or adynamic puerperal fever*, — *a.* *simple* — *β.* *complicated* with predominant affection — (*a*) *of the blood* — (*b*) *of the fluids and peritoneum* — (*c*) *of the fluids, serous surfaces, and soft solids generally* — (*d*) *of the blood, the uterus, or of the uterus and appendages* — (*e*) *of the internal surface of the uterine vessels, substance of the uterus, &c.*

45. iii. *Of the Conversion of Type, Form, &c.* — The above types, forms, and states, not only may result from some one or more of the above circumstances (§ 43.), but they also may be variously changed and modified by them, during the course of the disease — a simple state of fever becoming more intense or complicated, according to determining influences — the intermittent type becoming irregular or complicated, or passing into a simple, severe, or complicated remittent, and this latter into the continued type, frequently with predominant affection, either of the nervous or vascular system, or of some important viscus, or of both. This change of a slighter into a severer disease, and of simpler states into those which are more complicated, commonly arises from the circumstances just stated (§ 43.), and more especially from those concurring and determining causes about to be enumerated (§ 64, 65.); and is much more frequent than an alteration from a severe to a slighter form of fever, as that of a continued to a remittent, or of the latter to an intermittent type, which, however, sometimes occurs.

46. V. *TERMINATIONS. — Fevers terminate* — 1st, in a return to health; — 2dly, in some other disease; — and, 3dly, in death. *A.* *A termination in health* is favoured — *a.* by a previously sound constitution, and a spare habit of body; — *b.* by the absence of great intensity of the remote causes, and by their nature; those which are slight, or which proceed from endemic sources, or act singly, being less noxious than those arising from living animal bodies crowded together, or from the sick, or from various associations of animal effluvia, and of other causes; — *c.* by the absence of unfavourable influences and accidents, physical or moral, during the progress of the disease, — *d.* by a complete removal from the continued operation of the exciting, and even of the predisposing, causes during the treatment, and by the advantages of wholesome air and judicious management; — *e.* by the easy circumstances and equable mind of the patient; — and, *f.* by the occurrence of a crisis. The *modes* by which fevers terminate in health, are — 1st, by crisis, to the production of which art can only indirectly tend, but still tends very powerfully in some cases; — 2dly, by a resolution of the disease,

without any critical discharge. This is the most frequent mode observed in the fevers of this climate; and results, in a great measure, from the treatment adopted for them, particularly in their early stages, which generally interferes with, or prevents the occurrence of, the natural evacuations constituting *crises* (see this article). It is chiefly when artificial evacuations have not been pushed far, that crises manifest themselves.

47. *B. Terminations in other diseases* are owing — *a.* to previous disease, or the condition of particular viscera at the time of attack; — *b.* to the severity and concurrence of the causes, and the intensity of the disease; — *c.* to local determinations supervening during the progress of fever, giving rise to complications; — *d.* to improper treatment, as a too heating regimen, the continued use of cathartics, or the adoption of such as are too irritating; — *e.* to incomplete or imperfect crises; — *f.* to the too early or too liberal use of stimulants or tonics during the disease, or during convalescence; — *g.* to the continued operation of the causes during treatment; — *h.* to the occurrence of new, determining, or superadded causes, as crowding of the sick, bad ventilation, mental perturbations, in the progress of the malady; — and, *i.* to neglect, and to a blind confidence in the efforts of life. *The diseases* which may be thus superinduced, are — *a.* inflammations of particular organs; — *β.* engorgements, obstructions, and enlargements of glandular viscera, particularly the spleen or liver; — *γ.* effusion of serous fluids into shut cavities, as into the peritoneal and pleural sacs; — *δ.* partial or general anasarca; — *ε.* ulceration or abscess of mucous surfaces — chronic diarrhoea and dysentery; — *ζ.* hæmorrhage from mucous membranes; — *η.* inflammation of some part of the vascular system; — *θ.* apoplectic, paralytic, or epileptic seizures; — *ι.* mania and insanity in some one of its forms.

48. *C. A termination in death* is favoured — *a.* by constitutional vice, excessive vascular fullness, and a bad habit of body; — *b.* by the intensity of the cause and of the disease; — *c.* by the continued operation of the chief causes; — *d.* by the nature of the complication; — *e.* by neglect or improper treatment; — *f.* by unfavourable crises; — and, *h.* by the other circumstances just mentioned (§ 47.) as productive of consecutive diseases. — This result cannot be imputed to any single change. Two or even more of the following are evidently concerned in its production: — *a.* Extreme suppression of organic, nervous, or vital power; — *β.* Lesions of organs arresting their functions, and impeding those actions necessary to continuance of life; — *γ.* Vitiating of the fluids, changing the condition of, or destroying, nervous influence and the rest of the vital manifestations; — *δ.* Exhaustion of vital power, and alterations of the intimate organisation of the viscera, as in malignant fevers; — *ε.* Organic injury sustained by the nervous system, especially its larger masses; — *ζ.* Diminished or exhausted irritability of the heart, the patient expiring as in fatal syncope; — *η.* Suffocation from effusion into the bronchi; — *θ.* Congestion of the lungs, heart, and large vessels, to an extent beyond the vital power of these parts to overcome; — and, *ι.* Deficiency of blood so considerable as to destroy the relative conditions of the contained fluid and

containing vessels; for when the tonicity, the organic contractility, of the latter is much impaired, as in the advanced stages of adynamic fevers, and the amount of circulating fluid is also greatly lessened, the vessels will be unable to accommodate themselves to their contents, and the consequences must necessarily be most dangerous, if not speedily fatal.

49. VI. OF THE APPEARANCES AFTER DEATH.

— *A.* — *a.* Cases have been met with, wherein the most careful examination has failed to detect any lesion, or strictly morbid appearance, in any of the general systems, or individual textures, or in the fluids contained in the large vessels. It must be admitted, therefore, that changes may take place in the nervous system, or in the blood, sufficient to cause the most acute disease, or even to subvert life, without being so gross as to be demonstrable to our senses; but allowing this, the fact now stated is important, inasmuch as it most materially affects the question as to the nature of fever. — *b.* Other cases have been observed — and much more frequently than the foregoing — in which the morbid appearances were not commensurate with the intensity of the symptoms referable to their seats, and were quite insufficient to account for a fatal issue. — *c.* Frequently also, lesions of parts have been discovered, which were not indicated by symptoms, or by the usual symptoms, or very slightly and imperfectly; those changes having been more or less, or even entirely, latent during life, although their nature evinced their existence and progress during the advanced stages of the disease. This circumstance may have arisen from an oppressed or exhausted state of the brain; or from the changes in the circulating fluid impairing sensibility; or, as Dr. ALISON suggests, in his very able and lucid exposition of the Pathology of Fever, from an enfeebled state of the circulation at the time when these local affections take place.

50. *B. As to the nature of the changes observed,* opinions are somewhat different. — Many writers have viewed them as purely inflammatory; others as consequences of irritation, or of inflammatory irritation; this condition being viewed by them as a lesser grade or modification of inflammation. It is important to entertain precise ideas as to their nature; and to mark the circumstances in which they differ from those changes indisputably resulting from pure inflammation, particularly as occurring in a previously healthy constitution. — 1st. The lesions observed in fevers rarely present effusions of lymph or pus, especially in the adynamic and typhoid fevers, — consequences commonly following true inflammation; and the cases in which these effusions have been detected, have been instances of local inflammation supervening in the course of the more sthenic or inflammatory forms of fever. — 2dly. The lesions or inflammatory appearances have been more superficial, diffused, and attended with a darker discoloration, and greater softening of the affected and adjoining parts, than in idiopathic inflammation. — 3dly. The appearances thus characterised, differ the more from inflammation, the lower the type of fever and the more vitiated the circulating fluids. — 4thly. They more nearly resemble erysipelatous inflammation, than any other. — 5thly. They are met with in certain tissues more frequently than in others; and, excepting deficient

cohesion and discoloration, are commonly limited to these tissues.

51. *C.* The organs most frequently altered in structure, are, the digestive mucous surface, the liver, the spleen, the bronchial surface, the lungs, and the brain and its membranes. But the frequency of the alterations of each differs widely in different fevers; the first and last of these textures being upon the whole most frequently and seriously changed. — *a.* The digestive mucous surface is very generally affected in some fevers, particularly in certain that are endemic, as in the fevers of Paris, and in warm or marshy countries. The alterations of it are often insidious, latent, or much greater than the symptoms indicated; and they differ from the appearances commonly resulting from common inflammation, in the dark discolouration attending them, in their being confined to spots or patches, and in the less frequent effusion of lymph. — They consist — 1st, of livid or brownish red patches, covered by a dark reddish mucus; — 2dly, of softening, tumefaction, or thickening of the discoloured spots; — 3dly, of infiltration of the submucous tissue with dark or sanious fluids resembling small ecchymoses or internal petechiæ; — 4thly, more rarely of effusions of small portions of lymph in spots scattered over the membrane; — 5thly, of abrasions, sloughings, and ulcerations of this tissue, either sparingly scattered, or aggregated, — the latter most frequently in the lower ilium, or near the termination of the ilium. These changes are most common in the parts of the membrane occupied with PEYER'S and BRUNNER'S glands, but they also occur in the mucous membrane itself. Their frequency in different parts of the canal in fevers is the same as stated in the article DIGESTIVE CANAL (§36.). — These lesions are seldom seen alone. They are most frequently accompanied with changes in the mesenteric glands and in the encephalon, and are obviously advanced consequences of the general disease; as they are observed chiefly in the more protracted cases. They are the common causes of the intestinal hæmorrhages, of the severe pains, and the sinking sometimes occurring in the latter stages.

52. *C.* Alterations of the liver and spleen are much less frequent in this country, than in warm climates, and the countries of the south of Europe. — *a.* The change in the liver consists chiefly of congestion, injection of its vessels, softening, and enlargement. — *b.* The bile seldom presents a healthy appearance, either in the gall-bladder or in the hepatic ducts. — *c.* The affection of the spleen is most common after the periodic fevers of miasmatic localities; and consists chiefly of great enlargement, softening, and even gangrene. — *d.* The pancreas and kidneys are not often altered in structure, and the peritoneum still more rarely, excepting in puerperal fevers, and after perforation of the digestive canal.

53. *D.* The lesions of the respiratory and circulating organs are frequently very important. — *a.* The fauces and larynx sometimes are covered by an aphthous exudation, or are œdematous, infiltrated, tumefied, and softened; but the larynx is seldom affected to the extent of impeding respiration, unless in eruptive fevers. — *b.* The bronchial mucous membrane is often injected in patches, of a dark red or livid hue, somewhat thickened and softened, and covered by a discoloured, viscid,

and frothy mucus. — *c.* The pulmonary parenchyma is occasionally œdematous, or condensed by infiltration of a dark fluid, and at the same time somewhat softened. The changes in the bronchial surface and in the substance of the lungs often co-exist; and are also attended by gravitation of the fluids to the more depending parts of these organs; and by exudation of the more serous portions, — alterations which are not alone consequent upon death, but which often precede it, and constitute the "*Peripneumonie des Agonisans*" of LAENNEC. The changes, moreover, in the respiratory organs, particularly in the typhoid states of fevers, are often attended with lesions within the cranium and in the digestive mucous surface. — *d.* Gangrene of the lungs occurs only when inflammation of them supervenes in the course of fever; and the same remark is applicable to alterations of the pleura or pericardium. Inflammation of these latter textures sometimes takes place during convalescence, owing to premature exposure, and during the decline of fevers, particularly eruptive fevers. — *e.* The heart is sometimes softened, and its substance discoloured, particularly in adynamic or malignant fevers; and occasionally a sanguineous serum is found in the pericardium. — *f.* The blood in the cavities of the heart and large vessels is often also more or less changed. (See art. BLOOD, § 128.)

54. *E.* The lesions within the head most frequently consist of a morbid increase of the serous exhalation from the encephalic membranes, especially in the ventricles, and beneath the arachnoid; but the amount of the effusion is seldom very considerable. The blood-vessels within the cranium, especially of the pia mater and substance of the brain, are frequently turgid with a dark or fluid blood. Slight extravasations of blood are also rarely observed. These appearances have frequently little or no relation to the coma existing in the latter stages; and the same may be stated as to the changes in consistence which are sometimes seen in the substance of the brain, — these changes, however, being neither uniform nor frequent. — The *dura mater* is rarely affected.

55. *F.* Lesions are not so common in the spinal chord as within the head; but such as occur there are similar to these just stated. No uniform connection has been established between the morbid appearances in this situation and the pain in the back and loins, or other affections of the voluntary muscles, although some pathologists believe that these symptoms depend upon congestion or effusion within the spine.

56. Upon the whole, the changes observed in particular parts are chiefly advanced consequences of the disease, the most violent or malignant states of fever often being evinced rather in the altered colour, elasticity, and cohesion of the tissues, than in grosser lesions; these latter being most commonly superinduced on the former. It is important, however, to distinguish them from lesions which have existed before the occurrence of fever. The blood and all the secreted fluids are evidently more or less diseased; although it is difficult to show in what the change of these consists. (See BLOOD, § 115, and 128.)

57. VII. THE PROGNOSIS of Fevers is of the utmost importance as respects a knowledge of the changes taking place in their course, and of the

signs and tendency of these changes, as well as the reputation of the physician.—It is often difficult, owing to the mutability of the disease, and to the liability to err in appreciating those signs by which changes of the functions and of the organisation are indicated, particularly when the chief manifestations of life, and sensibility and organic contractility, are more or less impaired or perverted during the course of fever. The prognosis depends, generally, upon the following circumstances:—*a.* The nature and intensity of the predisposing, exciting, and concurring causes;—*b.* The character of the prevailing epidemic, or epidemic constitution;—*c.* The type, form, and state of the disease;—*d.* The states of the various functions, and of nervous and vital energy;—*e.* The congruity of the symptoms, and various contingent phenomena;—*f.* The influences, treatment, and regimen to which the patient is subjected;—and, *g.* The *entical* or other changes which may take place.

58. *A.*—*a.* The *predisposition* caused by debility, acute sensibility, or a plethoric and cachectic habit of body; a previously morbid, or congested state of the internal viscera, particularly of the liver, bowels, and spleen; and advanced age; increase the danger from fever. Some *epidemics*, however, most frequently attack the young and robust, and prove even more fatal to them. But, although *sporadic fever* may be also common in this class of patients, it is less dangerous in them than in the foregoing.—*b.* The *exciting agents*, particularly specific animal miasms; their concentrated form; the concurrence of several causes, either contemporaneously or in quick succession; their prolonged action, or continuance during the disease; and certain of the circumstances, inducing unfavourable terminations (§ 48.); render the prognosis much more serious. Some importance should also be attached to the character of the prevailing epidemic, as respects its open or insidious form, and the effects following a treatment appropriate to the usual states of the disease.

59. *B.*—*a.* The *intermittent type* is less serious than the remittent, and this latter than the continued; but the more the fever is inclined to change, to become irregular, or to pass into one of a graver character, the more serious it is. The more complete the intermission, or the remission, so much less is the danger; and the more disposed continued fevers are to evince a remitting form, the more favourable is the circumstance. The longer fever has continued, the more difficult will be the cure; and relapses are more unfavourable than first attacks.—*b.* The *inflammatory and sthenic species* are much more generally favourable than the *adynamic forms*.—*c.* The *simpler* the fever, the more certainly will recovery take place; and the more *complicated*, the greater is the danger. The *adynamic form*, with *predominant affection*, of an important internal organ, especially the intestinal mucous surface, or the brain, or the lungs, is accordingly amongst the most dangerous; more especially if the vascular system and circulating fluids, or the soft solids, also become vitiated.

60. *C.* The *more* that the *organic nervous influence* is suppressed, diminished, or disordered throughout the different viscera, the more unfavourable should be the prognosis; the functions of

the viscera, the state of the fluids and secretions, and the appearance of the soft solids, evincing the extent of the disorder and of the danger.—*A* weak, small, and quick pulse; a dark, dry, and contracted tongue; profuse, offensive, viscid, and unnatural perspirations; watery, foetid, flaky, membraniform, and unhealthy stools; discoloured, scanty, and brown urine; livid or discoloured nails, fingers, eyelids, lips, and nose, independently of the cold stage; a discoloured, dark, and dry mouth and throat; and an offensive and penetrating odour proceeding from the patient;—are dangerous symptoms. A pulse of 120 or upwards, unless in the puerperal state, is unfavourable, and so much the more so as it is above this number. A brown or black coating, and deep, reddish fissures, or a dark or livid colour of the tongue; stridor of the teeth; a movement of the lips and lower jaw as if eating; firm closure of the jaws and lips; extreme anxiety at the præcordia; tumefaction, tenderness, or pain of the epigastrium, hypochondria, or abdomen generally; tympanitic or flatulent distension of the abdomen; copious or repeated discharges of blood by stool; a sudden irruption of the catamenia, and an equally sudden disappearance of them; a moaning, weak, quick, abdominal, or gasping respiration; coldness or rawness of the expired air; hiccup; excessive increase, or diminution, or irregular distribution, and otherwise morbid state, of the animal heat; sunk features; rapid emaciation; great difficulty or impossibility of acting upon the skin by sinapisms or blisters; an earthy, or deadened, unnatural, lurid appearance of the external surface; yellowishness of, or petechiæ and livid or purple blotches on, the skin; and dark mucous sordes on the lips or gums, or sanious discharges from the latter or from the nose;—are very unfavourable circumstances.

61. *D.* The unfavourable symptoms, more directly depending upon the *cerebro-spinal nervous system*, are,—*a.* extreme pain of the head; excessive sensibility or depression of spirits; tumid or red countenance, injected watery eyes, contracted brows, &c., quickly passing into delirium, sopor, or coma; prolonged watchfulness, or early somnolency or torpor; convulsive movements, trismus or spasms of parts, great restlessness, and continued tossings; despair of recovery; and a presentiment or feeling that death will ensue.—*b.* And still more unfavourable are, early mental indifference, particularly to the issue of the disease; insensibility or sopor; profound coma, and difficulty of being roused; relaxation of the sphincters, and unconscious evacuations; excessive loss of muscular power; inability to retain any other than the supine posture, especially early in the disease, and in connection with extreme pain in the back and loins; falling down towards the foot of the bed; a position of the limbs and body, depending upon their gravity, and different from that usually preferred by the patient; inability to assume a posture different from that in which he is placed; picking with the fingers at the bed-clothes; subsultus of the tendons; catching after objects in the air; alternate dilatations and contractions of the nostrils during respiration; loss of voice or speech; trembling of the tongue, or inability to protrude it; an open mouth, or relaxation of the lower jaw; difficulty of deglutition; and dilatation and insensibility of the pupil.

62. *E. Unusual or incongruous symptoms* also denote danger, especially if the patient is more depressed by, or sinks faster under, the disease, than its apparent severity should warrant. The presence of severe symptoms, of which he makes little or no complaint, is much more dangerous than restlessness and anxiety when the symptoms are not so severe. Unquenchable thirst, the tongue being moist, and febrile heat moderate, the absence of thirst, the tongue and mouth being dry, and the temperature high; and remarkable craving for food before remission of the symptoms, the tongue remaining dry, &c.;—are unfavourable symptoms; the first indicating dangerous lesions of the stomach and liver, the second oppression of the brain, and the third inflammatory action of its substance, with extreme debility.—An early collapse of the countenance, or a pale lurid hue of it, with rapid emaciation, indicates a very dangerous form of fever, with vitiation of the circulating fluids. The more complete the change in the expressions, appearance, and habits of the patient, during the early stages of the disease, the greater the danger. A remarkable acuteness of the senses of hearing and sight is more unfavourable than an opposite condition. Changeableness of the urine, especially if it becomes limpid and scanty, from being copious and turbid, or ceases to deposit a sediment; an unnatural sound on deglutition; a marked or unusual sinking, or protrusion of the eye; a diminution or an enlargement of the objects seen, or double vision; openness of the eyes during sleep, or sopor; the patient supposing himself in a different bed or house to his own; and his urging a removal to his friends, or to a church, or to the altar;—all denote danger.

63. *F.* The more mild, open, and uncomplicated the disease, or devoid of any of the above unfavourable signs, the more certain will be recovery. The occurrence of crises at due periods, and their spontaneous and full evolution, are also very auspicious. But if the critical evacuations are imperfect, or if the exacerbations, or aggravation of particular symptoms, usually preceding them, only are observed—the efforts being thus abortive—or if the disease afterwards become more severe, danger should be apprehended; especially if the tongue be drier, the secretions more disordered or suppressed, and organic nervous power further diminished after such attempts. (See art. CRISIS.)

64. VIII. CAUSES.—i. REMOTE.—*A.* The predisposing causes are not the same in all fevers; for there is a certain susceptibility of frame, which favours the action of the exciting causes of epidemic and of certain specifically infectious fevers, independent of the states that predispose to the sporadic occurrence of fever. There seems also to be a certain innate susceptibility to the infection of eruptive and yellow fevers, that is destroyed by an attack of the disease, the same infection not producing its specific effects a second time; and this susceptibility, particularly when yellow fever is epidemic, is generally connected with high irritability of the muscular system, vascular plethora, and a robust state of the frame.—The most influential of the predisposing causes are—dread of the disease; change from a cold to a warm climate; peculiar idiosyncrasy; acute sensibility and irritability;

the excessive use of food, especially animal food, and of spirits, wines, and malt liquors; moist states of the air and diminished electricity; prevailing winds from the south and east; fatigue and exhaustion of mind or body, from whatever cause; accumulations of bile on the biliary apparatus, and morbid colluvies in the prima via; insufficient and unwholesome food; a close and moist atmosphere; whatever lowers the moral and vital energies; and the general predisposing causes adduced in the article DISEASE (§ 30—38.).

65. *B.* The exciting causes are the preceding, particularly when several act contemporaneously, or with much intensity; as a moist, warm, and stagnant air, rapidly carrying off by induction the positive electricity of the frame; a saburral state of the prima via; accumulations of vitiated bile; and mental or bodily exhaustion; miasmata, terrestrial exhalations, and foreign gases floating in the air; emanations from decaying vegetable matter; the exhalations from crowds of persons or animals in a confined space and stagnant air, as in transports, camps, crowded barracks, prisons, &c.; the effluvia arising from putrid or decaying animal matter, particularly when concentrated, or mixed with the emanations from decomposed vegetable matters; the miasms generated by copious secretions and discharges from the sick, as in crowded wards of hospitals, particularly lying-in hospitals, close, crowded, and low apartments, &c.; effluvia specifically infectious, as those of typhus and scarlatina; the force of imagination, or the impression produced on the mind by the sight of a person in the disease; fear, dread, or terror, and any of the depressing passions acting long and energetically; remarkable exertion of mind and body, and consequent fatigue of either or both; defect of the natural or accustomed stimuli, as of food, drink, tobacco, opium, &c. Certain of the causes, as infectious effluvia, miasms, &c., are especially active, and may therefore be said to be the specific, efficient, or essential agents of the disease; whilst others, as fatigue, cold, defect of stimuli, and certain of the predisposing causes, may act merely concurrently, or consecutively, as respects the principal exciting agent, or in such a manner as to determine or aid its effects. I would refer the reader to what is advanced respecting the specific and determining agents and influences in the articles on the *Causation of Disease* (§ 55—63.), on ENDEMIC INFLUENCES, and on INFECTION.

66. ii. OF THE PROXIMATE CAUSE, or those Changes more immediately consequent on the exciting or efficient Agents of Fever.—*A.* Opinions of the ancients, and of former writers.—Fever has been considered as essential or distinct diseases from the earliest records of medicine; and the extent of the ravages then produced by them may be inferred from the circumstance of a separate divinity having been assigned to them in the Grecian and Roman mythology. The Greeks invoked their divinity by the appropriate name Πυρετός; the Romans by the appellation *Febris* (PLINY, l. ii. cap. 7.; et AELIAN, *Var. Hist.* l. xii. cap. 11. p. 566.). The latter even erected temples for her worship on the Palatine Mount, in the Via Longa (*Vico Longo*), and in the place of the Monument of Marius (VALERIUS MAXIMUS, l. ii. cap. 5. p. 55.).—The popular

dread which gave rise to such a medium or mode of deprecation* not only marks the destructive prevalence of fevers in these countries, but also indicates the noxious effects of the Pontine Marshes in the time of the Roman republic.

67. The earliest opinion of the ancient Greeks respecting the immediate cause of fever appears to have been that of ANAXAGORAS (PLUTARCH, in *Vita PERICLIS*, p. 155.); etiam ARISTOTLE, (*De Gener. Anim.* l. iii. cap. 6.) — the contemporary of HIPPOCRATES. He attributed all acute diseases to an abundance of bile. ARISTOTLE (*De Part. Animal.* l. iv. c. 2.) combated this doctrine; but it became prevalent nevertheless. HIPPOCRATES, instead of entering into speculations which the want of data and first principles rendered futile, set a better example, by directing attention to the varying phenomena of the disease, and to their relation with the vicissitudes of season, &c. PLATO (TIMÆUS, p. 497.; et GALEN, *De Dogmat. Hipp. et Plat.* l. viii. p. 324.) considered that fevers, and, indeed, all diseases, arose from a disproportion of the different physical elements which enter into the composition of the body. Continued fevers, he supposed to arise from superfluity of fire; a quotidian from abundance of air; a tertian from predominance of water; and a quartan from that of earth. This is, perhaps, the first attempt at explaining the types of fever. It appears to have had but little influence, notwithstanding its universal adoption, in changing the modes of practice already recommended by HIPPOCRATES.

68. The dogmatists (GALEN, *de Nat. Hum.* p. 279.) of the following age, in conformity with their doctrine, conceived fever to proceed from the abundance of bile, its quantity determining the type of the disease. The *maximum*, in their opinion, produced continued fever of an ardent character; a less quantity, quotidians; and the *minimum*, quartans. PRAXAGORAS (RUFFUS, lib. i. chap. 33. p. 109.) of COS, one of the most faithful followers of Hippocrates, adopted a similar theory, and endeavoured also to account for the cold stage of the disease, by supposing its source to exist in the vena cava. This opinion possesses some features of the more modern doctrine of congestion, which no doubt exists, both in the vena cava and other large veins, during the cold stage, as a part of the series constituting the diseased actions which obtain the name of fever. ERASISTRATUS was the first who contended for a connection between fever and inflammation (GALEN, *Comment. II. in l. de Nat. Human.* p. 27.). He conceived these morbid states to consist in a transfusion of the blood into the arteries, disturbing the spirit they contain, and giving it an irregular direction. The former he believed to arise from the presence of blood in the large arteries; the latter, from a congestion (*παρέκτασις*) of this fluid in the capillaries (*Ibid. de Venæsect. adv. Erasist.* p. 2.). He was equally averse from bleeding and purging, which had been long and generally in use in the treat-

ment of these maladies; and in conformity, as he supposed, with his theory, recommended spare diet, emetics, lavements, warm baths, frictions, &c. (*Ibid.* p. 15, 16.)

69. ASCLEPIADES, the founder of the *Methodic School*, adopted a great part of the doctrine of ERASISTRATUS respecting the fundamental corpuscles, and the *pneuma* or spirit of the dogmatists. He explained the heat which takes place in fever, by the motion of these corpuscles; and accounted for sensation, pain, &c. by a similar hypothesis (CÆLIUS AURELIANUS, l. i. c. 15. pp. 46, 48, 57.). According to him, fever consists in an increase of heat, and of the pulse (*Ibid.* l. ii. c. 33. p. 151.). The other phenomena of fever and of inflammation, he considered to proceed from a disproportion between the particles and their pores. The elementary corpuscles, he supposed to pass from the lungs into the heart and arteries, and to produce occasionally, during their volatilization from the body, an obstruction in the channels through which they circulate; the larger causing the most obstinate obstruction, and, consecutively, the most violent fevers; and the lesser, slighter attacks. The type of the disease was explained after the same manner. The longer the intervals between the febrile accession, the more subtle the atoms were supposed to be which had become impacted in the vascular pores (*Idem. Acut.* l. i. c. 13. p. 42.). ASCLEPIADES conceived that nature could do nothing of herself in removing this state, and that all must be attempted by the physician. CÆLIUS (lib. iii. c. 8. p. 469.) informs us, that "Asclepiades officium medici esse dicit, ut tuto, ut celeriter, ut jucunde curet." Agreeably to this maxim, he prescribed gentle medicines, and dietetic means, instead of the violent remedies of the empirics (CÆL. AUREL. *Acut.* l. i. c. 14. p. 44.). Enemata, bloodletting, dry cupping, frictions, gestation, exercise, bathing, and, more rarely, emetics, were the agents which he recommended. (PLINY, lib. xxvi. c. 3. p. 392.; CÆL. AUREL. l. c. et lib. iii. c. 8. p. 215.)

70. SORANUS (CÆL. AUREL. *Acut.* l. ii. c. 33. p. 153.) conceived fevers to consist in an absolute relaxation of the vessels and their pores. CASSIUS, the Eclectic (CASSI IATROSPHISTÆ, *Naturales et Medicinales Quæstiones*, Ed. CONR. GRESSNER. Tigur. 1562.), was of opinion, conformably with the chief doctrine of the Methodics, that they arise in consequence of a different arrangement taking place in the primary and invisible corpuscles; while he adopted the hypothesis of the more ancient dogmatist, by considering the increase in the temperature to be the result of friction between these particles, disengaging their integral heat. The views of fever adopted by the Eclectics, led to few modes of practice which had not been previously employed. HERODOTUS (ORIBASIIUS, *Collect.* l. vi. cap. 28. p. 228. *et passim*), the disciple of AGATHINUS, who embraced more of the pneumatic system than of any other, placed great confidence in warm bathing and in sudorifics. These he considered to be serviceable, by fortifying the *pneuma* or spirit, and assisting it to expel heterogeneous particles. He attempted, also, to determine, with more precision, the time and circumstances in which bleeding, as recommended by HIPPOCRATES, ought to be prescribed.

71. GALEN (*De differ. Feb.* lib. i. *passim*) attri-

* The following is from a votive tablet to the goddess:—

Febri. divæ. Febri.
sanctæ. Febri. magnæ.
Camilla. Amata. pro.
filio. male. affecto. p.

TOMMASINI, in GREVIUS, *Thesaur.*
Roman. Antiq. t. xii. p. 867.

buted the varieties of fever to a degeneration of putrefaction of the humours, and to a certain change in the pncuma, developing an unnatural degree of heat. He supposed the heart and arteries to participate consecutively in this derangement, and to produce the subsequent phenomena. Continued fevers, according to him, had their chief source in an alteration of the pncuma, and of the humours; quotidian in a degeneration of the mucus; tertians in a similar change of the yellow bile; and quartans in a putrefaction of the black bile, which he considered the most slowly moved, and to require the longest period for the production of the paroxysm. The doctrine of Galen continued to be almost implicitly and universally adopted for many ages; and even down to modern times, it has had its partisans. The writers in medicine who flourished during the decay of the Roman empire, and the Arabian physicians, introduced but few modifications of his theory.

72. AËTIUS (*Tetrabibl. II. serm. ii. cap. 54. et passim*) and PALLADIUS explained the phenomena of fever in a nearly similar manner to GALEN. The former paid particular attention to the good effects arising from cool apartments, and ventilation, during treatment; and employed the therapeutical means recommended by HIPPOCRATES and GALEN. While PALLADIUS (*De Febribus, cap. 9. p. 30.*) admitted the opinion respecting the degeneration of the humours, he considered the disease to arise, also, from other causes—such as external or internal irritations, engorgement or suppression of the secretions and transpirations, and putrefaction of the blood itself.

73. During the seventh and eighth centuries, the Arabians attributed fevers to superabundance of impure or thick blood, which they conceived to be connected with a similar state of the bile, and other humours. They pretended, although not very appropriately, to dilute the former by purging, and to evacuate the latter by bleeding. AARON of Alexandria, and RHASES (*Contin. lib. xvii. cap. 6. sect. 360. et passim*), introduced no change into the humoral pathology. They, however, determined with more accuracy the types of continued fever; and paid greater attention to their production, especially in an epidemic form, by the influence of seasons and of certain states of the atmosphere, than had been bestowed upon the subject since the time of Hippocrates. ALI (*Abulfarg. Hist. Dynast. p. 326.*), surnamed the Wise, a physician of the tenth century, deserves notice, more from his recommendation of emetics, as prophylactics against that state of the humours which he supposed to be productive of fever, and on account of his employment of bleeding in intermittents, than from any innovation which he made in the received theory. AVICENNA (*SPRENGEL, Hist. Med. vol. ii. p. 358.*) appears to have introduced the greatest change in the doctrine of GALEN of any of the Arabian writers. He attributed the phenomena of fever, and other acute diseases, more to a superabundance of the different humours, than to a degeneration of their constitution. GILBERT*, an English

physician, in the middle of the thirteenth century, entertained the opinion, that as the changes which supervene in the humours are infinite, so the phenomena of fevers may be equally various. He defined fever to be a greater heat than natural, developed by the heart, and propagated by means of the arteries throughout the body, which deranges the other functions in its course, and promotes the further degeneration of the humours which first gave it origin. He admitted, that the heat of the body was not materially increased in many cases, and not at all in others; and that his definition was consequently incomplete. He, however, endeavoured to get rid of the difficulty by involving it in a cloud of scholastic subtleties.

74. ARNALD of Villanova (*Breviar. lib. i. cap. 26. p. 1121. et passim*) introduced astrology into the doctrine of fever, by attributing derangements of the humours to the influence of the heavenly bodies. MENGHO BIANCHELI (*De Omni Gen. Febr. et Ægritud. Venet. 1536, fol.—a rare work*), an Italian physician of the fifteenth century, gave a similar definition and theory of fevers to that already given by GILBERT. MICHEL SAVONAROLA (*Practica Canonica de Febribus, cap. ix. f. 36.*), a professor at Ferrara, about the same period, deserves mention on account of the view which he took of the influence of climate in modifying the pathology and phenomena of fever. There are few other authors who wrote during the middle ages, deserving of notice. All of them either more or less implicitly adopted the doctrine of Galen, or mixed it up with a farrago of scholastic subtleties and astronomical suppositions.

75. The removal of the trammels of the schools, and the revival of medical science in Europe, may be dated from the writings of J. FERNELIUS (*Opera Pathologica, &c. sec. iv.*). This eminent author and H. AUGENIUS (*De Febribus, sec. ii. c. 4. p. 50.*) were the first to impute the proximate cause of fever to changes in the living solids. They denied that the fluids constituted any part of the organisation, and consequently inferred that their influence in the production of the disease could not be primary. They very justly, however, admitted their consecutive derangement. FELIX PLATER (*Praxis Medica, vol. ii. c. 2. p. 39.*), one of the first writers who, since the revival of learning, turned attention to the true source of medical science—accurate and intimate observation—stated that, when the sensibility of a part is disordered by an excessive increase of its animal heat, the result is fever, the type of which he conceived to depend upon the particular fluid which is affected. He believed that, when the fluids contained in the vessels of the mesentery are disordered, fever assumes an intermittent type; and that the further the part whose sensibility is affected, is removed from the heart, the longer is the fever in being produced. Enough,

endeavours to solve, considered in relation to the time at which it was written, deserves transcription, and evinces also the metaphysical partialities of the author. "Wherefore is the vegetating or vital principle destroyed at death, and not the intellectual? Because the vegetating or vital principle is derived from matter, and may be regarded as its simple product. Consequently it must necessarily cease to exist with the derangement and destruction of the materials which produce it. The intellectual principle, on the contrary, is not a simple form; it possesses different attributes, not derived from the materials of the body, and therefore must endure after death." (Fol. 245, 246.)

* GILBERTI *Anglici Compendium Medicinæ, tam Morborum Universarium, quam Particularium, non solum Medicis, sed et Chyrurgicis utilissimum*, edit. MICH. VENET. DE CABELLA, 1510, 4to. This production of our countryman is curious, on account not only of its medical but also of its metaphysical and dialectic character. The following proposition, which he states, and immediately

however, has been stated to show that his facts are more valuable than his doctrine.

76. THOMAS CAMPANELLA*, the celebrated Italian metaphysician and pathologist of the sixteenth century, discarding the opinions of ARISTOTLE, conceived that the vital spirit, which is produced from the most subtle of the animal humours, and is nourished by the blood, is concerned in the production of all diseases, although itself undergoes no change, being only irritated or excited by the æriform matters and flatuities contained in, or proceeding from, the fluids. He considered that, as respects its nature, fever can scarcely be called a disease, since it results from the reaction or the efforts of the vital spirit to resist vitiation and putrefaction of the fluids, and thus to preserve life. He attributed the crisis and critical days to lunar influence, and explained the action of remedies on the principle of their exciting or reducing the temperature of the body. VAN HELMONT (*De Febribus*, c. 16. p. 783.) ascribed fever to the influence of the archæus or vital principle.—Although the foundation of the doctrine, which afterwards became so generally adopted, owing to the form it assumed in the hands of HOFFMANN, CULLEN, and others, was laid by these writers, another theory was soon afterwards promulgated. Owing to the increasing enthusiasm with which chemistry then began to be cultivated, the *chemical pathology* first proposed by PARACELUS (*Op. Omnia Med. Chémico-Chirurg.* 4to. Basil. 1589.), and supported by SYLVIVS (*Op. Med.* 4to. Amst. 1679.), WILLIS (*Oper. Omnia*, 4to. Geneva, 1680.), KERGER, BORELLI (*De Motu Animal.* pars i. et ii.), WEDEL (*Physiol. Med. et Pathol.* 4to. Jenæ, 1679.), and others, obtained a very general support; and although all the phenomena of fevers were not explained by some according to the principles of this school, yet its doctrines were conveniently adduced to account for various states of disorder.

77. It is unnecessary to notice the dreamings of FLUDD, DIGBY, MAXWELL, GREATERAKE, and others, of the sect of the Rosicrucians, which appeared early in the seventeenth century, as to the nature of fever. It is impossible to cast even a glance at the ravings of this sect, without entertaining ideas the most humiliating of human nature and intellect. Yet they found followers in Europe, particularly in Germany, as late as the middle of the eighteenth century; and, even now, emanations of their doctrine may be traced in some of the reveries which have recently been promulgated in that enquiring country. Leaving opinions calculated only to excite the most humiliating suggestions respecting the extent of human knowledge, and equally abasing reflections on the state of medical science in this country at that epoch, we arrive at a period presenting opinions more in accordance with calm and unbiassed reason than those immediately preceding.

78. The writings of SYDENHAM (*Opera Omnia*. Leyd. 1742, 8vo. *best edition*) tended to dissipate the "thick-coming fancies" of the humoral

and chemical pathologists; and, although tinctured by the chemical hypothesis, he nevertheless directed attention to the operations of nature. BAGLIVI (*Op. Omnia*, Ven. 1716, 4to.), at a later period, trod nearly in the same path as SYDENHAM; and, like him, attended to the prevailing character of epidemics, and viewed their phenomena in connection with the seasons and atmospheric vicissitudes. STAHL (*Theoria Med. Vera*, 4to. Matæ, 1737.), the disciple of WEDEL, forsaking the doctrines of his master, adopted a theory in many respects similar to that proposed by VAN HELMONT (*Op. Omnia*. Amst. 4to. 1664.) and CAMPANELLA. The psychico-chemical, or bio-chemical, hypothesis of STAHL subsequently received the support of SAUVAGES (*Nosol. Method.* 2 vols. 4to. Amst. 1768.), who, in addition to the efforts of the anima, the increased motion of the fluids, and augmented secretion and excretion of the salino-sulphureous particles, added the doctrine of BOERHAAVE, of accelerated circulation to remove a mechanical obstacle.

79. Although recent opinions as to the proximate cause of fever may be traced partly to FERNELIUS and others, yet it is to HOFFMANN (*De Generat. Febr.* Halæ, 1715.), the contemporary of STAHL, that we are indebted for some excellent ideas. He placed the chief source of motion in the nervous system, and considered that certain affections of nervous influence induce a general spasm of the extreme vessels, driving the blood from the capillaries into the large vessels, the heart and large arteries thus becoming irritated. A nearly similar hypothesis was soon afterwards framed by BOERHAAVE (*Prælect. Acad.* 2 vols. Goet. 1744.) from opinions entertained at different periods, more particularly from some of those promulgated by HOFFMANN. BOERHAAVE, adopting no single nor general principle, to which alone he referred the different manifestations of fever, kept his attention more especially fixed upon the relation subsisting between the exciting causes, and the actions they induce in the system, explaining at the same time the latter conformably with the pathological doctrines of the time. He considered that a quicker and a stronger action of the heart was induced, during fever, by an accession of the influence of the brain and the cerebellum, in order to overcome the resistance offered by the smaller vessels; and that fever was therefore an exertion of life to avert death. CULLEN (*First Lines of Pract. of Phys.* vol. i. p. 42.) illustrated, in a much more satisfactory manner, the doctrine of the living solid, as first proposed by FERNELIUS, and so ably extended, and, indeed, established, by HOFFMANN. The application of it to the theory of fever, which had been made by these and other writers, was more precisely explained by CULLEN, and more conformably with many of the phenomena. The opinions of this very acute and philosophical physician held a stricter reference to the early changes than had been generally entertained. The causes of fever he supposed to act by debilitating the nervous energy, inducing diminished influence of the brain, and consecutive atony of the superficial capillaries, accompanied with spasm; reaction of the heart and larger arteries supervening in consequence of this state. This doctrine was farther illustrated and modified by CURRIE (*Medi-*

* Born in 1568, and imprisoned for his metaphysical opinions from 1599 to 1629, when he was set at liberty by Pope URBAN VII. He afterwards went to Paris, where he died in 1629. (TIROSCCHI, *Storia*, &c. t. vii. p. 140.; CAMPANELLA, *Metaphys.* l. ii. p. 39.; et *Medecin.* l. i. c. 1. art. 1—4. 8vo. Leyd. 1635.)

cal Reports, &c. Lond. 1805, *passim*), GREGORY (*Lectures, &c.*), and W. PHILIP (*On the Nature of Fever.* Edin. 1807, p. 89.), the last of whom ascribed febrile reaction to a contest between the capillary and larger vessels; and it was most conducive to the employment of emetics at the commencement, and of diaphoretics through the course of the disease. Amongst the other neuropathologists, SELLE (*Rud. Pyretologiae Methodicae.* Berol. 1768, 8vo.) and TODE (*De Febrium Indole.* Hafn. 1769.) deserve notice. The former imputed fever to a peculiar condition induced in the nervous system in general; the latter referred it to a certain irritation in the common sensorium. SCHÄFFER (*Versuche, ii.* p. 44. *et seq.*) and THORER (*De Actione Systematis Nervosi in Feb.* Gott. 1774, p. 257.) ascribed it to a similar state of the nerves.

80. The experiments and arguments of HALLER having tended to establish irritability as a principle inherent in the muscular fibre, and independent of the cerebro-nervous system, furnished materials for doctrines founded upon such views. Several modifications of these successively appeared. STOLL (*Aphor. de Febribus,* p. 208.; *et Rut. Med.* vol. i. et ii. Vindob. 1768, 8vo.) considered fever to be morbidly increased irritability of the heart; J. C. JUNCKER (*De Spasmo Febrili Dissert.* Hal. 1769.) viewed it as augmented irritability of the heart and arteries, the nervous influence being, at the same time, diminished; ELSNER (*Varius Febris Status.* Regim. 1789, Döring. l. p. 110.) imagined it to be an irregular distribution of the irritability in consequence of certain internal stimuli; and DOSER (*De Febre.* Wirceb. 1795, p. 17.) ascribed it to a similar condition of this principle, the irritability of involuntary organs being heightened, and that of the voluntary lessened. Other pathologists called in the vital influence, in a more particular manner than had heretofore been done, in order to explain the phenomenon under consideration. KRAMP (*Fieberlehre nach Mechanischen Grundsätzen.* Heidelb. 1794.; *et De Vi vitali Arteriarum Diatribo.* Argent. 1786, p. 411.) referred fevers to an increase of the vital force of the vessels, beyond that which is requisite to the natural circulation of their fluids. FORDYCE (*Dissert. on Fever, passim*) imputed them to efforts made to overcome obstacles opposing a free and healthy circulation; and REIL (*Memorab. Clinic. &c.* fasc. iv. p. 107.) conceived them to result from an exalted state of the vital influence affecting chiefly the heart and blood-vessels. Along with this state of the vital energy, he supposed its disposition and qualities to be changed in the different kinds of contagious fevers; and hence the alterations which supervene in the constitution of the secretions, &c. SPRENGEL (*GALEN'S Fieberlehre.* Bresl. 1788, 8vo.) and C. F. HUFELAND (*System der Pract. Heilk.* Jen. 1802.) acknowledged, as the proximate cause of fever, a morbid reaction of the vital influence, which they imagined to take place throughout the system.

81. The doctrine of BROWN (*Elementa Medicinæ.* Edin. 1780, 8vo.) was remarkable chiefly for the manner in which the vital phenomena were explained by it. In this respect, also, the opinions of his contemporary DARWIN (*Zoonomia,* vol. iv. p. 333.) were no less distinguished, although greatly inferior to those of BROWN in point

of originality, simplicity, and philosophical sagacity. BROWN considered life to be preserved by the operation of the exciting fluids on the excitable solids, and health to be the result of their equal and reciprocal action. This action he considered to be deranged by the causes productive of disease. Fever he supposed to be an asthenic state of the system, arising either from the abstraction of the natural stimuli, or from the causes of the disease having directly or indirectly exhausted the excitability. The notions of DARWIN were merely more involved modifications and illustrations in different terms of the same theory. From these have arisen the new Italian doctrine, which attributes an opposite state of the system to fever from that imputed to it by BROWN. The opinions concerning the nature of disease, and the action of remedies, introduced by RASONI (*Della Febre Petecchiale di Genova; Del Metodo di Curare, &c. del Prof. G. TOMMASINI.* Bologna, 1821, &c. &c.), have produced so great a revolution in the principles of his master, as to entitle him to the honour of being considered as the founder of a new school.

82. The ideas of the humoral pathologists have been lately revived in Germany by CH. L. HOFFMANN (HILDENBRAND, *Institutiones Medicæ,* vol. i. p. 93.), WEDEKIND (*Nachrichten über das Französische, &c.* Leips. 1797, 8vo.), and HERRZIG (*De Febribus in Geneve, Colon.* 1790, 8vo.). They suppose some change analogous to putrefaction to supervene in the blood, which, irritating the vessels, produces fever. At a still later period, the opinions of the bio-chemists have been attempted to be restored. J. C. STARK and G. F. PARROT (HILDENBRAND, l. c.; and HUFELAND'S *Journal, passim*) attributed the proximate cause of the disease to an excitation and disturbance of the calorific process, and to the abundance of carbon in the blood. G. C. REICH (*Von Fieber und dessen Behandlung.* Berl. 1800, 8vo.) assigned a defect of oxygen in the organisation as the cause; J. C. BÄHRENS (*Über Fieber und Sautsäure.* Leip. 1802.) imputed too great an abundance of this substance to the system during fever; and J. C. HARLES (*Neue Untersuch. über das Fieber.* Leip. 1803.) referred the whole phenomena to the agency of electricity.

83. Although fever and local inflammation may arise simultaneously from concurrent predisposing and exciting causes, or from epidemic influence, yet the identity of both diseases did not become an article of pathological belief, until towards the close of the last century. RIVERRIUS (*Prax. Med.* sec. xvii. c. 2.), indeed, had very justly stated, that acute and malignant fevers very rarely run their course without inflammation of some viscus: but he remarks, in a manner worthy his high reputation, that the superinduced inflammation is different from that which is primary or idiopathic. Other writers had conceived, from the predominance and character of certain symptoms occurring in the progress of fever, that inflammatory action is no infrequent attendant upon it. COITER, of Groningen, was surprised when he found no inflammatory appearances within the head, in cases where the cerebral symptoms were very remarkable;—and WILLIS long afterwards supposed fever to be an inflammation of the spirits (*spirituum phlogosis*). Dr. GRANDVILLIERS is, however, the first writer, who

has distinctly ascribed fever to inflammation of the brain, he having remarked, in 1757, this organ especially affected in an epidemic characterised by malignant symptoms; and Dr. WENDELSTADT, in his description of an epidemic that prevailed in 1794 and 1795 in Wetzlar, attended by delirium in some cases, by catarrh or pneumonia in others, or by both delirium and pneumonia, considered inflammation of the brain to have occurred from the commencement. Still the existence of essential fever cannot be said to have been called in question, until the appearance of the works of PLOUCQUET (*Exposit. Nosolog. Typhi*. Tubing. 1800.) and CLUTTERBUCK (*Inquiry into the Seat and Nature of Fever*. Lond. 1802.), in which this disease is ascribed to inflammation of the substance of the brain. This doctrine was soon afterwards controverted by Dr. BEDDOES (*Researches concern. Fever as connected with Inflam. &c.* 8vo.); but MARCUS, of Bohemia, forsaking the pathology of BROWN, became a convert to it, and its most zealous supporter (*Ephemer. der Heilk.* b. i. st. 2. &c. 1809.); and other writers of inferior note espoused the doctrine both in MARCUS's *Ephemérides* and in HORN's *Archives*.

84. Shortly afterwards, another theory of fever made its appearance; and in France, at least, attracted considerable attention, owing to the copious writings of BROUSSAIS and of his pupils. This pathologist maintained that the mucous membrane of the digestive canal is the primary seat of fever, and presents the most general and unequivocal lesions after death; affections of other organs being merely consequent upon, or sympathetic of, disease of this part. Although several writers, especially RAHN (*Briefwechsel, &c.* p. 250. Zurich, 1787.), and BEDDOES (*Op. cit.* p. 63.), considered the gastric system most frequently affected in fevers, it was reserved for BROUSSAIS to conclude that "all the essential fevers of authors are to be ascribed to gastro-enteritis, simple or complicated." (*Exam. des Doct. Méd. &c.* t. i. p. 34.)

85. These two theories are the most important of those which have had reference to the local origin and seat of fever. They are manifestly founded on narrow views of the deranged actions consequent upon prolonged mental depression and anxiety — upon change of climate, season, and weather — upon the operations of endemic agents and epidemic influences — upon the action of various infectious miasms — according as each or several of them may affect persons differently predisposed, by temperament or diathesis — by habit of body and constitutional energy — by the state of the secreting and excreting viscera — and by the circumstances in which they are placed. They appear also to be deduced from mistaken conceptions of the actual sequence of the disordered actions characterising the various species of fever — sporadic, endemic, epidemic, infectious, &c. — however they may be associated or complicated with more or less local disease, either at their commencement, or in their progress.

86. The opinions which have recently been most adopted on the Continent, especially in Germany, are those which were taught by J. P. FRANK (*De Curandis Hom. Morbis, &c.* t. i. p. 34.) and V. N. ab HILDENBRAND (*Institut. Pract. Méd.* t. i. p. 96.). The former of these writers

confesses that he despairs of conveying any exact idea, or even of coming to any satisfactory conclusion, respecting the proximate cause of fever. He thinks, however, that fever may be viewed as resulting from irritation induced by an unaccustomed stimulus, the powers of life reacting, or making efforts at reaction, in order to remove it. HILDENBRAND states nearly the same proposition in different words, in concluding that the cause of fever is to be found in a morbidly increased reaction of the vital forces, owing to the irritation of a morbid stimulus. He further remarks — 1st, That all fevers are caused by an absolute or relative irritation, and consequently that they are all at their commencement irritative; — 2dly, That the reaction of fever never follows mere debility, although it is attended by debility; and that the debility of the vital powers is always secondary and the effect of the morbid irritation, or, adventitious as in the progress of the disease. — Admitting that it is difficult to explain — although I think it quite possible — how reaction of the vital forces can take place in the system in consequence of a cause primarily producing debility, more especially in the part where the impression is primarily made; still it is evident that all the causes of fever are not positive stimuli or irritants in their primary action, and consequently that their immediate effects on the surface to which they are applied are not exciting. Indeed, we have no evidence that the effects which are proximately consequent upon their application, are similar to those which uniformly result from those stimuli, with the action of which we are acquainted. Stimulating effects undoubtedly follow, remotely, in a majority of instances, but they supervene in consequence of intermediate operations taking place in the system itself.

87. The opinions of Dr. JACKSON are not materially different from those of HILDENBRAND. He considers the material cause of fever to be of an irritative kind; — that it enters the body by the absorbents of the first passages, proceeding into the circulation; and that it produces the febrile act by irritating the extreme series of organic capillaries, thereby occasioning subversion of the existing mode of action, and giving rise to changed or unnatural forms of action, through which the different secretions and functions are diminished, increased, or modified, in various ways and degrees.

88. I am not aware that any opinion has been promulgated different from those now briefly stated, up to the period when my own views as to the pathology of fever were published. Dr. ARMSTRONG was the most copious and recent writer on fever at that period; but, after an attentive perusal of his work on typhus, and of his published lectures, I am unable to ascertain what his views are, or wherein they differ from those generally entertained at the time, especially from those previously published by Dr. JACKSON, excepting that he particularly insists upon congestion, as an important pathological state of some forms of the disease; — but in this he merely followed STAHL, JUNCKER, R. SPRENGEL, JACKSON, and some other older as well as contemporary Continental writers. Upon the whole, his views, both pathological and practical, are so contradictory and vacillating, that a reference cannot be made to them with any degree of confidence.

89. IX. PATHOLOGICAL STATES—i. The EARLY

CHANGES IN FEVER.* In approaching the pathology of fever, there are certain circumstances to be kept in view: — *a.* That the chief causes, particularly malaria and animal effluvia, exert a noxious or poisonous influence upon the economy: — *b.* That these agents, usually tainting the surrounding atmosphere, when acting injuriously on the frame, pass along with it into the lungs during respiration, — the extensive surface there exposed to the tainted air; the organic properties, relations, and functions of this surface; the constant renewal of the air brought in contact with it, &c., favouring the action of these agents in this quarter in preference to any other with which they can have any communication: — *c.* The uncertain period that elapses between the time at which the morbid impression is made, and that at which it develops the fully formed malady; this period being usually of several days' duration, often much longer, and occasionally very much shorter, or almost instantaneous, especially when the cause is intense and the predisposition strong: — *d.* The general character of symptoms constituting the formative and invading stages (§ 33. 35.): — *e.* The state of function or vital manifestation throughout the frame, and the evident changes in the fluids and solids, in the various periods of the malady: — *f.* The complications and local determinations which supervene in the course of fever, and the periods at which they present themselves: — *g.* The external appearances and nature of the lesions observed after death, the seat of these lesions, their number and extent, and the relation they bear to the symptoms during life: — *h.* The obvious differences between the structural changes and those usually consequent upon common inflammation: — and *i.* The frequent absence of any lesion sufficient to account either for the symptoms or for death.

90. Existing opinions as to the nature of fever, particularly as respects the changes immediately following the exciting causes, may be reduced to the following: — 1st. That fever arises from inflammation, seated, according to some, in the brain, and, to others, in the digestive mucous surface, but sometimes also reflected upon the brain: — 2d. That it depends upon congestion of the large vessels and internal viscera: — 3d. That it proceeds from the direct contamination of the circulating fluids by its material cause, — the nervous symptoms, local affections, inflammations, &c.

* The views embodied in this chapter, and indeed throughout the whole of this article, which are not assigned to some other writer, especially those on the *Nature and Complications of Fever*, were promulgated by me on various occasions, and in different works, since 1819. In 1820, 1821, and 1822, they were published in the *Foreign Medical Review*, the *Medical and Physical Journal*, the *London Medical Repository*, and other works (see the *References*). In the winter of 1820 and 1821 they were fully stated, in answer to the views of Dr. CLUTTERBUCK, during a discussion at the London Medical Society, in which that able physician and myself were chiefly engaged, for three successive evenings. They were also fully developed in my lectures from 1824 to 1827, and in the Westminster Medical Society, as reported in the medical journals of the day. My experience of fever had been considerable previously even to the earliest of these dates. I had treated the most malignant types and complications of fever in the most pestilential climates within the tropics; I had closely observed the typhoid forms of it which prevailed in Germany and France soon after the late war; and had seen and treated it as it presented itself in various parts of Great Britain since the year 1810. I state this, in order to show that whatever opinions are here offered, similar to those contained in works which have appeared subsequently to 1821 and 1822, are certainly at least not derived from them.

appearing in its course, arising from the action of vitiated blood upon the organs: — 4th. That the causes first affect the cerebro-spinal nervous system, the phenomena of fever arising from the changes produced by them upon this system: — and, 5th. That the morbid impression is first made upon the organic or ganglionic nervous system, and, owing to the circumstance of this system actuating the circulating, secreting, and excreting viscera, is manifested, in an especial manner, by the changes observed in the state of vascular action, in the animal temperature, in the functions of secretion and excretion, in the circulating fluids, and in the other functions which are more or less intimately dependent upon the ganglionic system. (See my views respecting this system, in the *Appendix* to M. RICHERAND'S *Elements of Physiology*, p. 556: and as to its pathological relations, &c., particularly in connection with the causation of fever, in the *Lond. Med. Repos.* vol. xvii. p. 376.)

91. *A.* The doctrines imputing fever to inflammation of the brain, or of the digestive mucous surface, are subverted by nearly the same facts and considerations: — *a.* Inflammatory appearances are not uniformly observed in fatal cases, and *a fortiori* cannot generally exist in those which recover. — *b.* The lesions which actually exist, although possessing certain of the characters usually ascribed to inflammation, are wanting in others, especially those indicating sthenic, or purely inflammatory action; therefore these lesions, as stated above (§ 50), are either not the consequence of inflammation, or the result of an inflammation remarkably modified from the common or idiopathic kind, by some superadded cause, or by pre-existing changes in the state of vital power, and of the circulating fluids, as will appear hereafter. — *c.* As the lesions, whatever their nature may be, are often inadequate to account for the symptoms, or for death, they are to be looked upon as contingent phenomena, or merely as the grosser portion of those changes, supervening throughout the frame; the whole group of symptoms, their succession, and the ultimate issue, depending more upon the functional disorder in the first instance, and the consequent changes in the fluids and general organisation, than upon the more palpable lesions of structure, which occur in different parts from various influences determining or exciting a predominant state or grade of the morbid or general action, during its course, to some particular viscus or structure. — *d.* The inflammatory appearances observed after fevers are not co-ordinate with those produced by inflammation, nor are they identical with, or even similar to, them (§ 50.). — *e.* These lesions are not restricted to the same situation or viscus, the inflammatory complications or local determinations whence they proceed, being chiefly seated in different organs, in different cases and different epidemics; — the stomach and bowels being principally or predominantly affected in one case or in one epidemic; the head in another; the lungs in a third; the liver in a fourth; according to various predisposing, concurrent, and determining influences, as previous disorder, mental distress, the temperature, season and weather, the state of the air and of the locality, fatigue, exposure to cold, &c. — *f.* The existence of vascular congestion, although more

common than the other inflammatory appearances, in no way supports this doctrine of fever, inasmuch as it may be present to the extent observed in most instances of fever, without causing much disturbance, or it may supervene shortly before death, or even immediately after dissolution. But readily granting its existence even early in the disease, it is merely one of several changes consequent upon others much more important, as will appear in the sequel (§ 92.).—*g.* Those who believe in the inflammatory origin of fever do not agree respecting the particular viscus which is its especial seat; some assigning one organ, others another: the diversified complications, or predominance of morbid action in one viscus, or even in several, over others, in different cases and epidemics (*e*), furnishing them with the only arguments they can assign in favour of their opinions.—*h.* The changes supervening in the blood, in the secretions, and in the general organisation, during the progress of fever, cannot be explained by, or reconciled with, its origin in local inflammation.—*i.* The appearances considered inflammatory, and to which this class of pathologists refer in support of their doctrine, most frequently take place in the progress of fever, and seldom at its commencement, as shown by a careful observation of the symptoms.—*k.* The tendency to a favourable termination, and to natural crises, is much more remarkable in fevers, than in inflammations.—*l.* The general characters of fevers vary remarkably in different epidemics and epidemic constitutions,—a circumstance not remarked in respect of inflammations, or in a much slighter degree,—and lastly, the *juvantia* and *ludentia*, in both respectively, indicate a great difference between them. The extent to which depletions can be carried in both, and the frequent benefit derived from very opposite measures in the former, and which are injurious in the latter, are also no mean proof; for although vascular depletions are often requisite to control the local determinations or even inflammations which supervene in the course of, or early in, fevers, yet they cannot, owing to the state of vital power, be carried so far as in pure inflammations; and, although evacuations are most necessary in some epidemics, and tonics or stimulants injurious, still the former cannot be practised to the same extent, at least in this climate, as in the phlegmasiæ; whilst in epidemics of an opposite character, bleeding is often injurious, and opposite means are required,—a circumstance not observed respecting inflammation.

92. B. Certain of the arguments now urged are equally applicable to the doctrine of congestion, or irregular distribution of the blood.—*a.* The espousers of this opinion do not agree among themselves as to the chief seat of congestion; but granting that congestion very frequently, or even generally, exists at some period of the disease, especially in the large vessels adjoining the heart, it is only one link of the chain of morbid causation and action, itself being caused and attended by, as well as inducing, other changes equally important. Besides, those instances which occasionally occur of remarkably great congestion of the large vessels of internal viscera, as from asphyxy, &c., are not followed by the phenomena of idiopathic fever; and although, as I shall have to show hereafter, many of the worst forms of fever

are attended by congestion as one only of the various changes that characterise them, yet others of a slight kind, as ague, are accompanied with still more remarkable congestion during the cold stage of each paroxysm, without further mischief than the subsequent reaction which it aids in developing.—*b.* When congestion becomes considerable, it is referrible to the noxious influence of the exciting causes exerted primarily upon the organic or ganglial nervous system, and consequently upon the vascular system; the action of the heart being thereby weakened, and the tone and resiliency of the vessels impaired; and hence, when the morbid impression on the former is very intense, the effects produced upon the latter are also severe, congestion being only one of these effects.—When, in consequence of the persistence of the morbid impression, or change primarily produced in the ganglial nervous system, the effects upon the heart and vessels continue, the resulting congestions, with the other concomitant lesions, either cannot be removed, or are removed with difficulty; the heart being rendered unable to exert a due reaction in order to overcome them; the vessels being incapable of that degree of tonic resistance necessary to a healthy circulation and a regular distribution of blood; and the capillaries being impaired in all their functions, owing to the state of nervous power influencing them, and of the circulation in them. Thus congestion is established as one of the more evident lesions that follow the primary changes in fever,—but only as one of subordinate importance.

93. C. To the doctrine that imputes fever to the direct contamination of the circulating fluid by the material cause, the following objections may be urged:—*a.* The febrile cause, acting as a poison, should instantly affect the appearance of the blood if it made its first and principal attack in this way; but, when the cause is energetic, the effects, instead of progressively and gradually appearing, as they necessarily would do in this case, instantly manifest themselves in the functions of the nervous systems, more especially of the organic nervous system, and in the functions of the organs actuated by it. I shall, however, have hereafter to show, that the blood is the next animal constituent that becomes affected, although frequently in no very manifest manner, at first, especially when disease slowly develops itself upon the exciting causes.—It should not be overlooked, in our researches on this subject, that agents which especially affect or depress the organic nervous influence, produce also co-ordinate effects upon the vascular system and on the blood itself, owing to the intimate connection subsisting between these two systems.—*b.* In cases where the morbid impression has been already made, either by malaria, or by infectious effluvia, the full development of the disease may be prevented during the first or second stage, by substances which produce a powerful restorative or tonic action on the nervous systems, particularly that of organic life,—an effect that could not result if the blood were the primary or principal seat of the disease. A powerful stimulant or tonic will instantly cut short an ague, even when given at the commencement of the cold stage,—an effect that would vainly be looked for, if its chief seat were in the blood.—*c.* The phenomena and progress of

those diseases, as scurvy and purpura hæmorrhagica, in which the blood is especially altered, furnish analogous indications that it is not the primary nor sole seat of fever, but that it is merely secondarily affected, to an extent varying remarkably in different fevers and epidemics; and that the change in this constituent is only a part of the general state of disease—is only one of the many lesions forming idiopathic fever.—*d.* The abatement of fever after crises has been considered as evidence of the primary affection of the blood. Granting that morbid matters carried into the circulation, or generated in it from a morbid seminum, are eliminated from it in the form of crises, or by less manifest evacuations, still this is no proof that the blood is primarily or chiefly changed; but merely that it is one of the animal constituents affected, more particularly in certain forms of fever, as the eruptive and infectious; for we often observe critical discharges occurring without any permanent benefit, as in remittents; and recovery taking place in others without any crises. Whilst, therefore, a numerous class of fevers, especially the periodic and simple continued, present little or no evidence of contamination of the blood in their course, unless they change their characters and become complicated, a different class, as the adynamic and malignant, presents as little evidence of this change at their commencement; the vitiation of the circulating current appearing either consecutively upon the morbid impression made upon the nervous system of organic life, or nearly contemporaneously with this impression, and in a less manifest degree, although progressively advancing, owing to the affection of this particular system, and its influence upon the circulation. But the arguments which are about to be offered in support of my views as to the primary lesions in fever, will more clearly show in how far the blood is concerned in causing many of the phenomena of fever in its more severe forms.

94. *D.* The doctrine that the causes of fever first affect the cerebro-spinal nervous system is invalidated by the following considerations:—*a.* This system either does not send nerves, or it supplies but few nerves, and those often indirectly, to the organs especially or essentially affected in idiopathic fevers, as the heart, blood-vessels, secreting viscera, lungs, &c.—*b.* That the chief avenues to this system open to the invasion of the exciting causes, are the organs of sense and the cutaneous surface. Of these, the sense of smell is the principal. Although this sense is evidently impressed by several of these causes, when acting intensely, and admitting that the brain is somewhat affected in consequence, still the effect produced in this quarter seems inadequate to explain the chief, and far less the whole, of the early phenomena.—*c.* In some instances, the intense operation of the effluvia generating fever, has produced its effects almost instantly, and even caused death itself with equal rapidity,—a result, which the total annihilation of the cerebral functions could not produce; but which would necessarily follow the interruption or suppression of the influence transmitted to the heart and lungs by the nervous system of organic life.—*d.* The generation of fever within the body itself cannot be explained upon the supposition that the cerebro-spinal nervous system is primarily and solely, or even

chiefly, concerned in the production of the disease; but may be readily solved by means of the nervous system of organic life, if we take into consideration its functions and structural relations, especially with the vascular system, the circulating fluids, and the excreting viscera. (See DISEASE, § 65.)—*d.* The early lesions, whether of function or of organisation, characterising the first as well as the advanced periods of fever, cannot be accounted for by assigning the cerebro-spinal nervous system as the primary seat of the disease; for,—1st. As this system cannot influence the action of the heart and the state of the vessels, excepting through the medium of the organic nervous system, and thus only to a very limited extent, changes in it do not explain the alterations of vascular action, and still less the vitiation of the blood;—2dly. As it does not control animal heat, so it cannot induce those remarkable extremes and morbid states of temperature distinguishing the malady;—3dly. As it does not supply, nor materially influence, secreting surfaces and glands, so it cannot give rise to those early changes of function which they present, nor to those lesions of structure which they often subsequently experience;—4thly. As it does not materially affect the actions of assimilation and nutrition, so it cannot occasion the remarkable changes they present in fevers;—and, 5thly. As it does not present aberrations of function, in the slighter and simpler states of fever, equal in degree to those manifested by the viscera chiefly supplied by the nerves of organic life; and as, when such aberrations supervene in a remarkable manner, they are generally consequent upon those of the organic nervous and vascular systems and of the blood itself, so the primary impression made upon it must be much less energetic than is supposed by those who support the present doctrine; although I may grant that it partakes, in some measure, or in some forms of fever, of the morbid impression especially and principally made upon the nervous system of organic life, and extended to the organs which it actuates.

95. *E.* That the efficient agents of fever act primarily and chiefly upon the organic or ganglionic nervous system, is evident from what has been now adduced; and is further proved by the following facts and inferences:—*a.* The intimate connection of this system with the organs of circulation, respiration, assimilation, and secretion, on the one hand, and with the cerebro-spinal nervous system on the other, and the influence exerted by it over their functions in health, are sufficient to show, that morbid impressions made upon it must necessarily affect all the organs and parts, with which it is related.—*b.* The functions primarily disordered in fever, and chiefly affected in its course, are precisely those which are especially subjected to the influence of this system. As we cannot, consistently with our knowledge of the animal actions in health and in disease, infer that a grave and permanent disorder of any one function can exist, unless either the influence that actuates it is impaired, excited, or otherwise altered; or the structure of the organ, which is the instrument of the function, is more or less affected; we are necessarily led to inquire as to which of these sources the disorder is to be imputed. Having inferred from the nature and extent of the disorder, from

the causes in which it arose, and the suddenness and manner of its occurrence, as well as from various other circumstances, that it does not consist of lesion of structure, we are therefore compelled to adopt the former alternative, and, from the kind of disorder, to infer the manner in which the influence actuating the organ is affected. Thus, observing that respiration, circulation, secretion, and animal heat are primarily and especially disordered at the commencement of fever, and that various other morbid phenomena are consequently produced, and finding no structural or local change to account for the affection, we refer it to the state of the influence which actuates these functions. Anatomical and physiological evidence concur in showing that the nervous system of organic life is chiefly concerned in the production of those functions; and therefore it may be inferred that this system is first impressed by the causes of the disease.

96. But it is not merely requisite to show the particular system first affected, but also to ascertain, as nearly as possible, the *nature* of the affection. This, however, can be only a matter of inference from the kind of disorder manifested in the functions especially subjected to the influence of this system. What, therefore, is the general character of the disorder which these functions first evince?—1st. The respiratory actions are inadequately performed, volition being often exerted in order fully to dilate the lungs, and the changes in the blood are imperfectly produced;—2dly. The action of the heart is weakened, and the tone of the pulmonary vessels lowered, so that the circulation is languid, irregular, &c., and congestion supervenes;—3dly. Secretion and excretion are impeded or interrupted, animal temperature diminished, and all the functions indicate at first depression or suppression of the organic nervous influence. There is, however, reason to suppose that this influence may not only be *depressed*, but that it may be otherwise *altered*, according to the cause which affects it, particularly by specific infectious miasms. It is chiefly to this circumstance, that the opinions of JACKSON, FRANK, HILDENBRAND, and others, respecting the irritation excited by the material cause of fever, is to be imputed. Whether the alteration in question be called an irritation, or any thing else, is immaterial, if the term adopted convey any idea of what the change is, in most of the circumstances in which it occurs. But if by this irritation be meant a form of excitement, the term is applicable only to the state of vascular action often consequent upon, and attended by, the alteration of nervous influence, and not to the state of the influence itself. The whole that we know of the matter, from observation of the earliest phenomena, is, that the change evinces diminished power or influence of the system of nerves actuating the organic functions, and very frequently an otherwise altered or morbid state of this influence which cannot well be described, but which is variously modified in different fevers, and is generally attended by depression; these conditions still continuing in diverse grades, although vascular reaction supervenes, which, when it becomes excessive, increases them, and, in consequence, hastens on disorganisation. From this it will appear, that the exciting causes of fever first depress or otherwise alter, or both depress

and alter, the healthy influence exerted by the nervous system of organic life. That they primarily irritate or excite this system does not appear from the phenomena, unless either of these states associates itself with some other morbid condition which deflects it from its usual forms; but of this we have little proof, unless it be found in the stage of reaction. This much, however, is apparent,—that certain causes seem to depress the organic nervous influence more than others; and that some alter it more from the merely dynamic states, and impress it with a specifically morbid character.

97. But, whilst disorder of this influence is thus considered the chief and primary constituent of the morbid impression made by the causes of fever upon the economy, it may be asked, Is the impression entirely limited to this quarter? or are the cerebro-spinal influence, and the circulating fluid itself, also partially and primarily affected?—1st. As to the former of these, it may be inferred, from a consideration of the circumstance of the nerves of one of our senses being extended over the upper part of the respiratory passage—the entrance to a most important and vital organ—in order to convey, by their reports, intimations of the presence of such gases or vapours, as, if received into the lungs, would prove injurious, that the more intense causes will act in some measure upon the brain, although in a comparatively slight and evanescent manner. The lungs evidently digest the air received into them, as much as the stomach digests the food; and the entrances into both organs are guarded by two sentinels—the senses of smell and taste—taking cognizance of whatever passes into them. But in cases where injurious effects follow the ingestion of hurtful matters, is it in the stomach or in the nerves of taste that the morbid impression is to be looked for? and if it be in the former, and not in the latter, that they are to be found, no more should we infer, as heretofore, that the morbid change is first produced on the brain, and not on the nerves of the lungs, when noxious effects follow the respiration of a tainted or infectious air—recollecting always, that respiration does not mean simply the passage of air into and out of the lungs, but the actual digestion of this air by them, the important changes excited by its constituents upon the blood and upon the organic nervous influence, and those effected by this influence upon the blood, and upon the air received into the organ.

98. From various considerations and researches into the subject, in different climates, I infer, that, although the more intense causes may affect the brain, and thereby heighten and accelerate the effects upon the heart and stomach arising from the impression made upon the organic nervous system, yet their action in this quarter is evanescent; and, as I have shown (§94.), insufficient to explain the phenomena. Judging from my own sensations on having inspired an air so loaded with infectious effluvia as to be remarkably offensive to the smell, the morbid impression was first sensibly felt in the lungs themselves; numbness, weight, or oppression in the chest, was instantly felt; frequent forcible inspirations were made, and continued for long afterwards to be made, in order fully to dilate the lungs, which felt as if they were partially deprived of their resiliency; the pulse became weak, and the animal tem-

perature was lowered; but the functions of the brain were not impaired. In this case, the lungs were certainly the first organ affected, and almost instantly afterwards the action of the heart and the functions of the stomach. Instances, moreover, are not infrequent, in which the febrile cause has made its impression, and the patient has been removed from every chance of having that impression renewed; and it has not, until the end of weeks, and even months, given rise to its specific effects. In this case, is the cerebro-spinal system, or the nerves of organic life, or the blood, affected, and the seat of the latent, or almost latent impression? I have observed the phenomena occurring during this period, in cases of rabies, of small-pox, of measles, of scarlatina, of typhus, and of marsh or periodic fevers; and in every instance they have not indicated any affection of the cerebro-spinal system, but disorder more especially of the functions depending upon the nervous system of organic life. This period, moreover, is frequently shortened or prolonged; the symptoms attending it, diminished or aggravated; and the impending malady even prevented, by means which act more especially upon the latter system. Hence the importance of this inquiry; for by arriving at just conclusions as to the constituent part of the economy first affected, and the mode in which it is affected, we are the more enabled to guard against fever, or even to remove the morbid impression after it has been made, and before it has developed itself into open disease.

99. The opinion that the morbid causes even partially operate by first inducing changes in the blood, cannot be reconciled with the arguments already stated, and with others which may be offered, although there are circumstances which seem to favour it, the most forcible of which is the propagation of certain diseases by means of a virus, and the long period a virus or morbid miasm often takes to incubate or produce its full effects. But if we look closely into these very circumstances, we shall find that they are not so conclusive of the opinion they are adduced to support as is supposed; for in the case of an inoculated virus—the most favourable to the doctrine of primary contamination of the blood,—the consequent infection will be hastened by whatever depresses, and retarded by whatever exalts without exhausting, organic nervous power; it will be accelerated by the usual concurring and determining causes, as a close, foul, moist air, by cold, by excesses of any kind, and by despondency; and it will be retarded or even prevented by a dry and pure air, by the use of tonics, or what communicates power and increases vital resistance to the invasion of a noxious cause. The phenomena, also, observed between the application of the cause—whether a contagious virus, an infectious miasm, or an emanation from the soil—and the explosion of the malady, however prolonged the intervening period may be, cannot be referred to any alteration of the circulating fluids, that may not be shown to be entirely dependent simply upon the existing state of organic nervous or vital power. In rabies, in which the longest formative or incubating stages is observed, symptoms referrible to the organic nervous system are the first to appear, and the functions depending upon this system are those which especially lau-

guish during this period. The same is observed in agues, and in the specific infectious maladies. But even granting that a portion of the animal miasms passes into the blood, and vitiates it, the morbid impression is not the less made by them on the nerves of the organ, and not the less unproductive of the principal part of the phenomena more immediately supervening. But this topic is more fully illustrated in the article INFECTION.

100. In order to show what appears to be the common procession of phenomena consequent upon the impression of the exciting causes, I shall presume that a person in health, with no particular organ especially predisposed to disease, is exposed either to infection by the effluvia from a patient in typhus, or to the operation of marsh exhalations. In these cases the exciting causes, floating in the air, are received into the lungs, and, if they be concentrated or energetic, they slightly, although they may sensibly, affect the organ of smell in their passage. But their chief action is exerted upon the nerves of the lungs themselves. It may even be admitted that they also partially affect the blood during the digestion of the air which is their vehicle by the lungs: of this, however, we have no satisfactory proof; and as their direct operation on the nervous influence of this organ is sufficient to produce all the phenomena, it is unnecessary to assign an additional agency to explain them. The morbid impression having been thus principally made in this quarter, it is necessarily extended to those organs which are chiefly supplied with the same system of nerves; and thus the lungs, the heart, and blood-vessels, the digestive organs, and the secreting and assimilating functions, almost immediately experience the effects. As respects the lungs, their vital resiliency is somewhat impaired; hence the frequent and forced inspirations; and the changes effected by the air upon the blood, which, although chemical, are partly also vital or influenced by the organic nervous power of the organ, are more or less impeded. This latter fact I endeavoured to put to the test of experiment. In a paper written at the commencement of 1815, I had endeavoured to prove that many of the phenomena of fever were referrible to diminution of the changes produced in the blood by respiration; and in 1817, when engaged in ascertaining the alterations effected in the respired air, under various circumstances, I found, in two cases of ague and in one case of remittent, just before the cold stage of the former, and near the first accession of the latter, that the changes in the respired air were diminished from one fourth to one third their usual amount. These experiments were too few, and not sufficiently varied, but they serve to illustrate the subject.

101. The effect, then, of the morbid impression on the organic nervous influence of the lungs being to diminish the changes caused by respiration on the blood, and to render the pulmonary circulation more languid, one source of the alterations observed in this fluid in the early stages of fever is made manifest. These alterations, at this period, seldom extend beyond a darker or more venous appearance of the blood than usual, the crassamentum being often soft and imperfectly separated from the serum. Almost contemporaneously with the effect upon the lungs, the

action of the heart and the tone of the vascular system generally, become diminished. Hence the increasing languor of the circulation, the internal congestions, and the deficient secretion and excretion; these last, however, depending as much upon the state of organic nervous influence as upon the circulation in the secreting organs. The congestions of the large vessels, and the changes in the quantity and quality of the blood, consequent upon deficient secretion and excretion of its watery and noxious constituents, having reached a certain pitch, bring about vascular reaction, if the organic nervous or vital influence be not too far reduced, or otherwise altered, by the exciting causes; but when the morbid impression has been very intense, and the more immediate changes very great, reaction either takes place imperfectly, or does not supervene at all in extreme cases, vital power being insufficient to develop increased vascular action. Such appears to be so far the progress of the phenomena, as respects the organic functions. The cerebro-spinal manifestations are also early affected—in a slight and passing manner by the impression made by the noxious effluvia on the nerves of smell; but much more seriously by the influence exerted by the organic nervous system upon the brain and spinal cord, or extended from the former to the latter, and consecutively by the changes in the states of vascular action and of the blood.

102. *F. Consecutive Pathological States.*—When reaction thus supervenes upon either of the specific causes mentioned above (§ 100.), it may be variously modified according to the association of various grades of increased vascular action and of diminished or otherwise altered nervous or vital power, and to the local determinations or complications attending it. When, in consequence of the nature and intensity of the causes, relatively to organic nervous energy, the former do not depress the latter beyond the power of reaction, whereby the morbid impression is effaced, and the effects upon the different organs and on the blood are removed, the more sthenic forms of fever take place, vascular action is high, and nervous or vital power not greatly impaired. But when the nature and intensity of the causes are such, in relation to vital power, as greatly to depress or otherwise change it, the more adynamic forms are produced, and vascular reaction is much less energetic, the depressed state of vital power being a prominent and increasing feature throughout the disease. In some of the latter forms, vascular action becomes either excessive or tumultuous relatively to the state of nervous or vital power, owing to the effects produced by the secondary changes in the blood, upon the heart and blood-vessels, and on the organic nervous system, and rapidly exhausts itself, or passes into disorganisation; and in others reaction does not supervene, the tone of the vessels being progressively diminished, and the blood with the soft solids more and more changed. Hence result, in the last stages, discolouration, softness, flaccidity, lessened vital cohesion, and infiltration of membranous and parenchymatous tissues, with effusions of fluids from mucous and serous surfaces.

103. *G. Local determinations and complications* may attend fever from an early period, or appear

at any time during its course, or even at its decline; owing to the circumstances influencing its terminations (§ 47.), but especially to the following:—1st. To pre-existing functional or structural lesion of an organ or tissue;—2d. To the predisposing and concurring causes;—3d. To the nature and intensity of exciting and specific causes;—4th. To the character of the epidemic;—5th. To various determining or consecutive influences;—6th. To the effects of reaction upon certain viscera;—7th. To interrupted excretion;—8th. To the morbid states of the circulating fluids exciting disease, quickly passing into disorganisation;—and, 9th. To injudicious treatment.

104. *a. Pre-existing disease of a part*, especially when seated in the alimentary canal, brain, or lungs, aggravates fever and gives it a modified form. A loaded or congested state of the liver, also, in respect either of its vascular system or of its biliary ducts, often disposes to fevers, and imparts to them a bilious or gastric character. Various lesions observed after fever, and sometimes imputed to it, have existed previously, or have been merely aggravated by it, particularly those seen in the pleura and in the liver, and some of those found within the cranium.

105. *b. The predisposition* arising from the use of unwholesome water and food especially favour the low types of the disease, with lesions of the mucous follicles and membrane, which can hardly be said to be inflammatory, and contamination of the blood; that from excessive mental exertion or anxiety, increased affection of the brain; and that from gross living and intemperance, complications with disease of the liver, stomach, and bowels. The *concurring determining*, and *consecutive agencies*, not merely develop the action of specific causes, as shown in the article DISEASE (§ 61.), but they also complicate the fever produced. Thus cold both aids the operation of other causes, and occasions increased pulmonary disorder; and the influences of season, weather, climate, confined air, &c. cause aggravated affections of the intestines, or of the liver, of the brain, of the respiratory passages, or of the circulating fluids.

106. *c. The nature and intensity of the chief or specific causes* often determine the complication.—Malaria most frequently causes congestion of the liver and spleen; the emanations from persons affected by low fevers, aggravated affections of the digestive canal, of the brain, and often also of the lungs; and the exanthematous effluvia, their specific eruptions, and disease of the digestive mucous surface and pulmonary organs; these local aggravations of the malady appearing chiefly where the causes have acted most intensely relatively to the state of vital power and predisposition, or have been aided by concurring influences. The complications in fevers produced by the former of these causes are the least severe, and those arising from infection the most dangerous, owing to the states of vascular action, of vital power, and of the circulating fluids generally accompanying them; the first of these states being often excessive, or of an unfavourable kind; the second depressed or otherwise altered; and the third more or less changed from its natural condition, or even contaminated.

107. *d. The complications* are different in re-

spect of their seat, nature, and severity, and the states of local action, of vital power, and of the circulating and secreted fluids, in *different epidemics*, often independently of season, climate, weather, and locality, although these have much influence in many that are limited in their diffusion. Consequently, the complications are much more prone to pass into disorganisation in one epidemic than in another; but those occurring in the epidemics of warm countries are more uniform in their character and seat than those observed in the epidemics of temperate countries. It is chiefly upon a close observation of all the circumstances connected with their complications, that a successful treatment of epidemic fevers depends.

108. *e. Reaction or vascular excitement* occasions local determinations and complications, which generally present more or less of an inflammatory character; the brain, alimentary canal, the liver, or lungs, most frequently being the seat of the predominant affection, and evincing the effects of it after death. If, however, vascular action far exceed vital power, the superinduced local affection seldom presents many of the truly inflammatory characters, as shown above (§ 50.), and it often rapidly passes into disorganisation, or gives rise to sanguineous, serous or sanious effusions, but very rarely to the effusion of lymph or of albuminous fluids, unless in the most sthenic state of the disease.

109. *f. Interrupted excretion* induces complications frequently at far advanced periods of fever, especially implicating the bowels, the liver, and brain. They are generally of a most severe, although often insidious form, owing to their association with depressed or exhausted states of the constitutional powers; these states having been more or less concerned in causing the imperfect excretions, and with alterations in the blood, which the latter has contributed to produce; and they often quickly pass into structural lesions, not so much from the inflammatory or increased vascular action which attends them, as from the septic and contaminating effects of the retained excremential matters upon the tissues, and from their depressing influence on the nerves of the part.

110. *g. Morbid states of the blood* induce the most dangerous complications, and, like the preceding, most frequently at advanced periods of the disease, the mucous membranes, PEYER'S and BRUNNER'S glands, the brain, and the lungs, being the parts chiefly affected. As the changes in the blood are chiefly caused and attended by a depressed or altered state of organic nervous power, the local affections caused by them, whether they be characterised by increased vascular action or by simple congestion, generally pass quickly into structural lesions, especially of the mucous membranes, or give rise to effusions of a sanguineous, foul, dark, or sanious fluid, either from these membranes or from serous surfaces.

111. *h. Injudicious regimen and treatment* are much more frequent causes of aggravated local lesions in fever than is supposed. External heat or cold inappropriately employed; the improper use of stimulants and tonics; the neglect of suitable evacuations early in the disease; and the use of acrid or irritating purgatives; frequently occasion or heighten predominant affections of

the intestinal mucous surface, of the liver, and of the brain. Excessive doses, or the prolonged and inappropriate exhibition, of antimonials, especially tartar emetic, in the manner often resorted to in Italy, have evidently caused serious irritation and ulceration of the mucous membrane of the stomach and bowels, without producing either sickness or vomiting after its first operation in this way. The too early and free use of bark, or of quinine, in periodic fevers, or before morbid secretions have been evacuated, and congestions of the liver removed, has often induced serious inflammation and structural change in the liver.

112. *i.* It must be evident from the foregoing that the predominant affections or complications of fever must vary, not merely in their seat, but also in their intimate nature, in its different types and forms; the low and adynamic states being attended by those which are the least inflammatory, the most imperfectly indicated by the symptoms, and the most prone to pass quickly into disorganisation; this event, indeed, often being the first indication of their existence. It requires, therefore, a close scrutiny of the various functions to detect them, especially when they are seated in the *intestinal canal and lungs*. Although the complications in the former of these situations may be indicated by tenderness on deep pressure, by distension or fulness of the abdomen, and by the appearance of the evacuations, yet they may be present, nevertheless, without any such signs, even the stools evincing no very material disorder. When the stools are copious without any amendment, and particularly if they continue so, the pulse being weak, soft, and very frequent, and the skin harsh, lurid, or discoloured, we should dread the presence of disease of the digestive mucous surface and follicular glands; and if these symptoms be attended by flatulent distension of the abdomen, and by blood in the evacuations, this complication most probably exists. The complication with disease of the *substance of the liver* is often equally obscure in the adynamic varieties, more especially when the brain is much affected; for, although fulness and tenderness in the region of the organ, or a rising of this viscus high into the right thorax, as detected upon percussion, may sometimes be present, yet serious lesions may supervene without any of these indications being observed.

113. *k.* Most serious disease and even disorganisation may affect the *lungs*, particularly in the low forms of fever, without cough or pain being complained of. This organ, therefore, should receive due attention, and its state be inquired into by percussion and auscultation, which will very often detect bronchial affection, and hepatisation or infiltration of it, although these lesions may be either imperfectly or not at all indicated by the usual symptoms. When the pulse is very soft and weak; the lips, tongue, and skin are dark, lurid, or livid; the delirium is low or muttering; and the respiration is hurried and laboured; the changes effected on the blood in the lungs are evidently impeded, and the cause exists either in depressed nervous influence, or in more palpable disease of the respiratory apparatus, or even in both; for the latter is often the indirect consequence of the former. In the low forms of fever, the changes that supervene

in the bronchial surface, or in the substance of the lungs, as well as those that take place in the alimentary canal, possess but little of the truly inflammatory character, excepting capillary injection, sometimes with infiltration of a sanguineous serum into the adjoining tissues, or with effusion of a similar fluid from the injected surfaces.

114. *l. Predominant cerebral affection* less frequently amounts to actual disease, or passes into disorganisation, in fevers, than has been very generally supposed; the disorder most commonly existing in this quarter, in low fevers especially, being more functional than structural—depending more upon the state of organic nervous influence in the organ, than upon inflammatory or other lesions. The effusions and congestions observed in fatal cases, are probably in great measure *post mortem* changes; and, even granting their existence during life, they are often insufficient to account for the symptoms referrible to this part. Whatever the alterations existing within the cranium may be, there can be no doubt that, when the affection of the brain is very predominant, lesions in other situations are very seldom complained of, and with difficulty detected. The above complications, as well as others casually alluded to, will be more fully elucidated, when the particular species of fever come under consideration.

115. *m.* It is evident, from what has been stated respecting the pathology of fever, that a most scrupulous and minute inquiry into the states of organic nervous or vital power, evinced in all the functions, and of vascular action and tone—into the evidence of local congestions, or predominant visceral affection—into the existing functions and lesions of individual organs—and into the conditions and appearances of the secreted and excreted fluids, of the blood, and of the solids—should furnish the basis of our curative intentions, and direct the choice of individual means. Nor ought it to be overlooked, that the mutability of fever is so remarkable, that the pathological states actually existing at the time of investigation, may change their characters and even their nature, in an hour or two afterwards; that each successive stage is very different in the grouping of the phenomena, and in the conditions of vascular action and vital power, from that which preceded it; that serious complications or predominant affections may suddenly arise and become almost irremediable in a very short time; and, consequently, that the treatment devised should be promptly administered; and prescribed either with reference to the usual successions of morbid states, or merely for a period, in which no very important change is likely to take place.

116. *X. GENERAL TREATMENT.*—The treatment of fevers is *prophylactic* and *curative*. The former has been little attended to by writers, and but imperfectly understood; and the latter has too frequently been directed, without due attention to pathological states, and often with an imperfect knowledge of their seat and nature. Before a general view of the curative treatment of fevers is exhibited, a few remarks on their prevention will be necessary.

117. *i. PROPHYLACTIC MEANS.*—The prevention of fever should have reference—1st, to the avoidance of its causes, and the seclusion of those suffering infectious forms of it;—2dly, to

means which may destroy or dilute its more specific agents, and counteract their operation;—3dly, to measures calculated to fortify the frame against the impression made by them;—4thly, to means which may prevent the development of disease after the impression has been made;—and, 5thly, to a treatment calculated to arrest its further progress at a period when arrest is still within the reach of art. The first, second, and third of these are so fully insisted upon in the articles ENDEMIC INFLUENCE (§ 20.) and INFECTION, that little further need here be advanced respecting them; the remarks offered under these heads having especial reference to *periodic* and *infectious fevers* respectively.

118. *A. Measures calculated to fortify the frame against the impression of the exciting causes* often succeed in preventing fever, especially when these causes are of casual occurrence and of short continuance, or when their presence is known or suspected, and their nature tolerably understood. But in epidemics, particularly those which are pestilential, where these conditions do not obtain, means of this description generally fail, their causes being more generally diffused, and in almost continual operation. The measures resorted to, in order to resist the causes of fevers, should have reference to the habits and circumstances of the individual, to his constitutional powers, and his habit of body. All the predisposing causes should be carefully avoided. Vascular plethora ought therefore to be reduced, and vital power and resistance promoted where it is lowered. High irritability, vascular fulness, and rigidity of fibre, seem to predispose to several pestilential epidemics, especially to yellow fever; and, although these states will often resist for a long time the operation of marsh exhalations, particularly in temperate countries, yet such is not generally the case as respects persons migrating from cold to hot climates; for they commonly experience, in consequence of these states, much more violent attacks of fever than those who have been seasoned to the country; the fever in them often evincing inordinate excitement and re-action, and consequently assuming characters which have caused it to be confounded with the true or epidemic yellow fever. The most efficient resistance to the action of the causes of fever, is afforded by a due performance of all the organic and mental functions. Hence, whatever over-excites or depresses them will be injurious. Confidence, continued mental occupation, and moderate excitement, are especially efficacious in resisting the causes of most fevers. There is a moral courage sometimes possessed by persons, the weakest perhaps in respect of physical power, that enables them to resist infectious and epidemic influences, more successfully than the most robust, who are not thus mentally endowed.

119. The quarter in which the most active causes of fever invade the system should not be overlooked, for the casual or temporary operation of infectious effluvia, when their presence is anticipated, may be easily and certainly guarded against by the use of the aromatic spirit of vinegar, or by keeping a small piece of camphar in the mouth. When terrestrial emanations are present, care should be taken not to be exposed to the morning or night air, especially with an empty stomach, as they are then most concentrated; nor

to sleep in apartments upon or near to the ground floor, for the body is most susceptible of their influence on these occasions. When such precautions cannot be used, a cup of coffee should be taken before going abroad, and a pill with two or three grains of quinine and one or two of camphor at bedtime; but these means are of most benefit in cases of short residence in unhealthy localities, for which occasions I have directed the following pills with success:—

No. 220. R Camphoræ rasæ ʒj.; Quinina Sulphatis ʒss.; Pilul. Galbani Comp. ʒj.; Pulv. Capsici gr. xvj.; Balsami Canadensis, q. s. M. Fiant Pilulæ xxxvi., quarum capiat duas vel tres hora somni.

120. The system should not be stimulated by wines or spirits, unless better means are not within reach, and even then these should be used in very moderate quantity, otherwise exhaustion and its attendant predisposition will result from them. The same objection is applicable to cigar smoking; care ought also to be taken not to inhale the breath, or the effluvia proceeding from under the bed-clothes, or from the evacuations of persons in continued fevers, whatever means of resistance may be employed; but more especially with an empty stomach, or in states of debility or exhaustion, should this precaution be observed. During the prevalence of epidemics, of which infection is one of the chief elements, or causes of diffusion, strict seclusion can alone be depended upon. Still, other means should not be neglected. It has been supposed, that external irritation, or the discharge from an issue or seton, will prevent an attack of epidemic or pestilential fever; and cases have occurred to countenance the opinion, but they are not sufficiently conclusive. Upon the whole, a due regulation of the digestive, the secreting, and the excreting functions; avoidance of all causes of physical and moral depression; and a proper recourse to the additional means recommended to prevent INFECTION, in that article, are most to be depended upon.

121. B. After the morbid impression has been made, the development of fever may often be prevented, if the patient no longer remain subjected to the operation of the exciting causes. We have seen that disease is frequently many days in forming, the system manifesting slight disorder only during the time (§ 34.). The object on such occasions should be to enable the frame to maintain a successful struggle against the impression that has been made, and its more immediate effects. With this view, all the causes enumerated in the article DISEASE, under the name of *determining or consecutive* (§ 61.), should be carefully avoided, especially exposure to cold, to wet, and moisture; the use of cold fluids, and of cold, indigestible substances; excesses of every kind, and the common causes of physical and mental depression; and the patient ought to remove to a pure, dry, and open air. Tonics ought at the same time to be employed, especially such as determine the circulation to the external surface, improve the tone of the digestive organs, and promote the secretions and excretions, particularly those of the bowels and liver. When the actions of the bowels require aid, cold and debilitating aperients should not be prescribed. Warm and *stomachic purgatives* or laxatives, or these combined with tonics, are the most appropriate. When the impression has been energetic, and made by

infectious effluvia, an immediate recourse to *stimuli*, especially *camphor*, *ammonia*, aromatic spirits, spirits of nitric æther in tea, &c.; or, if these be not at hand, to warm wine whey, or brandy and water, will generally prevent any ill effects. The *diet* should be regular, moderate, nutritious, and easy of digestion; the stomach having nothing to do that it cannot perfectly accomplish. If these be found insufficient, a *warm bath*, followed by active friction of the surface; and if reaction have not supervened, *warm diaphoretics* may be directed. If the patient still continue to complain of the symptoms of the formative stage, an *emetic*, with aromatic adjuncts (see F. 198. 402.), should be exhibited, and repeated until it fully operates; after which the diaphoretics may be repeated, or a moderate dose of *calomel*, with five or six grains of *camphor*, and one or two of *opium*, may be given, which should be followed, in a few hours, by an active stomachic cathartic (F. 181. 216. 266.). These means have been employed by me in several instances during the formative stage of fevers, with perfect success. But in cases where we suspect inflammatory irritation to have commenced in the alimentary canal, and during the prevalence of epidemics characterised by this complication, emetics, particularly those containing tartarised antimony and acrid purgatives, should be withheld, and the other means be resorted to, especially the *warm bath*, to which stimulating substances may be added, and frictions of the surface. Internal irritants of the digestive mucous membrane should be also abstained from in the formative stage of the exanthemata, for in them this membrane is generally irritable and injected; and it readily becomes inflamed upon the injection of stimulating and acrid matters; the healthy development of the eruption being thereby prevented. It is chiefly in robust constitutions, and after the operation of other causes than infection, that severe shocks, by active emetics or cathartics, are best borne; whilst the other remedies, especially camphor, calomel, and opium, warm diaphoretics and diluents, tonics with camphor and ammonia, external derivatives, and warm, mild, but efficacious purgatives, are most suitable when the morbid impression has been made by infectious emanations. This treatment may not succeed in arresting the fever, but it will seldom fail of shortening the premonitory stage, and rendering the subsequent disease more mild or of shorter duration; for it frequently is observed that, when the formative period is allowed to continue, and to develop the series of changes to which it leads when left to itself, the consequent disease assumes a very severe or dangerous form.

122. C. The arrest of fever may be also successfully attempted, during the stage of invasion (§ 35.), or up to the commencement of vascular reaction, or excitement; but when once this period has supervened, the fever will run a regular course, although it will often be much shortened by treatment. Fevers, I believe, caused by infection are very rarely arrested after reaction is established. The means just advised for the formative stage may likewise be tried in that of invasion; but much discrimination is requisite in the choice of means. Camphor, ammonia, and warm diaphoretics and diluents, sometimes with opium, when the head is not affected; the warm bath, the vapour or heated air bath, and frictions subse-

quently; are the most generally appropriate. In robust persons, and where terrestrial emanations have been the chief cause, a warm emetic (F. 198. 402.) and active stomachic purgatives (F. 181. 216. 266.) may also be exhibited, but they should more rarely be ventured upon in other circumstances, for the reasons just assigned: the recipes now referred to, however, will not be attended with the least risk. When there is tenderness at the epigastrium, with other signs of gastric irritation and depression of nervous power, instead of an emetic or cathartic, a large sinapism, or a warm turpentine epithem, should be placed upon this region, and over a great part of the abdomen; or, in other cases, upon the insides of the thighs; but neither of these ought to be resorted to if reaction have supervened, nor continued after it has come on.

123. ii. CURATIVE TREATMENT.—The *indications* of cure in fevers are — 1st, to remove the exciting, and all other causes likely to exert an unfavourable influence on the patient, and to place him in a pure, dry, and temperate air; — 2dly, to moderate vascular action when it becomes excessive; and to impart tone and energy to the vascular system, in states of depression or exhaustion; — 3dly, to support vital power, especially when associated with imperfect reaction, or when resulting from depressed or exhausted organic nervous influence and vascular action; — and, 4thly, to remove local obstructions, congestions, determinations of blood, or predominant states of action, or other disease, in particular viscera. This last may be termed the *symptomatic treatment* of fever, the others the *vital*; inasmuch as they have especial reference to the states of organic nervous power, and of vascular action.

124. In endeavouring to fulfil these indications, there are various circumstances to be kept in view, viz. — *a.* The previous health, age, and condition of the patient, in relation to the existing states of vascular action and power, and of individual functions. — *b.* The nature, intensity, and combinations of the causes of the disease, and the unfavourable influences which still continue to operate, and cannot be removed. — *c.* The manner in which different pathological states modify the operation of many of the most active medicines. — *d.* As precise a recognition as the symptoms will afford, of the ever-changing conditions of vascular action, of nervous power, and of exhalation, secretion, and excretion during the course of the malady; and strict appropriation of the means of cure, not merely as respects their operation in health — their physiological action; but as regards their influence on disease, especially existing states of it — their therapeutical effects. The importance, and, indeed, the necessity, of attending to these circumstances in the treatment of fevers, is well illustrated by the action of antimonials, in their various forms and states. The potassio-tartrate of antimony is one of the medicines most generally employed on the Continent, particularly in Italy, as a *contra-stimulant*, in what is called, by the modern Italian school, the *stimulant-diathe-sis* of fever; and it is an excellent remedy in several forms of the disease, during the stages of excitement, in which it may be given in very large doses. But the tolerance of such doses depends mainly upon the states of vascular excitement and

of vital power, and on the repetitions of the medicine; for they may be remarkably injurious in states of low action, in the very young or in the aged, in persons previously ill fed, in fevers attended with predominant affection of the digestive mucous surface, especially when of a low type and caused by infection; it often occasioning in these, especially when taken in very large quantities, serious lesion of the mucous membrane of the stomach and bowels. Keeping, therefore, these *indications* and *circumstances* in view, the treatment of fever must be directed according to its type, its particular form, its varying conditions and complications, and its existing stage or period, and with due reference to the measures which have already been adopted.

125. *A.* The patient should be removed from the exciting, concurring, and consecutive causes, and be placed in as pure and dry an atmosphere as possible, in a large well-ventilated apartment; but out of the way of currents of air, and in an equable and moderate temperature. When an elevated situation or chamber can be selected, the advantage should not be neglected, particularly in large towns. The earlier in the disease that this intention can be fulfilled the better; as the more completely the functions of respiration are performed, especially as to the changes effected by it on the blood, the less risk there will be of future vital exhaustion, and of contamination of the circulating and secreted fluids. Nor should it be overlooked that, although the pulmonary functions are imperfectly performed during the formative and invading stages, they are more or less completely restored as reaction is developed, and they often assume their accustomed activity, unless the bronchial surface, or substance of the lungs, have been inordinately affected by congestion or determination of blood during the early stages; the subsequent activity of this organ contributing to restore the impaired purity of the circulating fluids, and to prevent or counteract much of the vitiation they afterwards would experience from an impeded elimination of hurtful matters, particularly in circumstances unfavourable to the due performance of the several depurating functions, of which the lungs are themselves one of the most important, and a dry, pure and temperate air, one of the most effective agents.

126. *B.* The moderation of excessive vascular action is obviously necessary; but the particular means by which it should be effected, and the grades of action that should be interfered with, are not so evident. These are points which must not be determined by theory, but inferred from extensive experience and observation. If the patient was previously in good health; if the causes were not remarkably intense, or are imperfectly known; if the symptoms do not indicate great excess of action, or serious irritation of any particular system, or determination to any viscus, or congestion; then little need be attempted, and certainly no active means should be resorted to, especially among the poor, and persons of a spare habit of body. In the rich and well fed, or those who are more plethoric, simple saline refrigerants and diaphoretics, mild aperients, and cooling diluents and diuretics, may be employed, rather with reference to consequent changes, than as respects the existing state of disorder — to the prevention of future lesion, the removal of ob-

structions, and the preparation of the organs for salutary or critical changes. These means exert a solvent or relaxing operation upon the capillary vessels; they promote secretion, soothe vascular irritation, equalise the circulation, and facilitate the excreting actions.

127. When vascular action rises above the state just mentioned, it should be considered excessive, and more energetic remedies employed. Inordinate action varies remarkably in grade, and somewhat in kind, with the causes which induce it, with the consequent state of organic nervous power, and with the constitution, habit of body, and age of the patient, from that just noticed, to the vehement forms, which are rapidly followed by exhaustion, by a dissolved or otherwise altered condition of the blood, by lesion of capillary action and tone, and by structural change, especially in mucous surfaces and parenchymatous viscera. The most intense forms of reaction, and consequently the most rapid in their course, often have nearly passed off before the patient is brought for treatment, the effects of morbid action being then only observed, and the exact nature of the disease frequently mistaken. But in proportion as the action of the heart and the pulse are strong, frequent, full, and hard; the countenance and surface injected, turgescient, and animated; the eyes bright and prominent; respiration full, deep, and laboured; animal heat increased, or acrid and burning; the excretions diminished or suppressed; the animal functions unbroken, consistent, and free; and the course of the disease, whether epidemic or sporadic, acute and rapid, and the type perfectly continued; so much the more active and immediate should be the means employed to lower the excited action on which these depend, and to prevent its dangerous tendency. — These means have been usually named from the morbid states they are employed in removing, as *antiphlogistic*, *antisthenic*, *contra-stimulant*, *refrigerant*, *lowering*, *evacuant*, &c., and are very numerous; although the remedies which are appropriate to particular forms of excessive action are much more limited.

128. *a.* *Vascular depletions* were resorted to by the ancients, generally with the view of diminishing inordinate action, or of diverting an impetuous motion of the fluids from vital organs; and observation taught them, that, when pushed far, with an intention of curing or arresting the progress of fever, they were frequently injurious. A nearly similar practice was adopted by the best writers, from HIPPOCRATES to SYDENHAM, who both illustrated it. SYDENHAM explicitly states, that bleeding is required to repress the tumultuous or irregular motions of nature, and remove the flux of blood from an important organ or part, to which the febrile impulse has determined it; and the ideas held respecting the practice, among judicious writers of recent times, nearly agree with the above, although they differ as to the employment of it in certain types and forms of fever. When the symptoms just stated (§ 127.) are present, bloodletting should be promptly and decidedly employed; and when the patient is removed into a pure air, beyond the influence of the causes, and is robust, plethoric, and young, it may often be carried to a great extent. This appears to have been the case with DOVER's patients. His account of the treatment of the fever

which broke out amongst his followers to South America was given by Dr. FRANKLIN to Dr. RUSH, and was a principal cause of the change which took place in the practice of the latter during the epidemic fever of North America in 1797. DOVER was a Buccaneer leader, and no mean physician, and practised both professions much in the same spirit. He ordered bleeding to a very great extent at the commencement of the disease, — a treatment successfully adopted in our own times, under similar circumstances; and which I have resorted to in the ardent fever occurring within the tropics. In a case, wherein I directed bloodletting before reaction had supervened, the loss of three or four ounces caused profound and prolonged syncope; yet, within four hours, when reaction had come on, fifty ounces were taken before any effect was produced upon the pulse; — and before the sun of the same day had gone down, forty more were abstracted at one time, — in all, ninety-four ounces within twelve hours. But the patients for whom this practice has been prescribed with success have been young, robust, or plethoric, and removed from the continued influence of the causes which produced the disease.

129. *a.* The extent to which bloodletting should be employed, and the good effects from it, will depend on the particular form and complication the disease assumes, on circumstances peculiar to the patient, on the character of the epidemic, and on the period at which it is resorted to. It may be injurious, from being carried too far, or not far enough, — and from being resorted to before reaction has supervened, or when the reaction is about to pass into exhaustion, or in cases in which it is not indicated. Its effects will depend upon the manner in which these and other circumstances are weighed by the practitioner; but it should not be overlooked, that it depresses the vital energies much more remarkably in fever than in idiopathic inflammations; and, when inappropriately or too freely practised, it prevents or retards salutary evacuations and crises; and either disposes to unfavourable changes, or renders convalescence difficult and prolonged. HILDENBRAND very justly remarks that, even in cases where the propriety of the practice is undoubted, a moderate quantity only should be taken away at one time, and the effects upon the disease, as well as the appearance of the blood, should be carefully observed, before its repetition be directed. This precaution is especially requisite at the commencement of epidemics, if depletion be employed late in the disease, and if vascular action be tumultuous, or much exceed nervous or vital power.

130. Large bloodlettings have been directed with the view of arresting or shortening the fever; and, when the person has been robust, the constitution sound, the cause not very intense, and its effects not very violent, the practice has occasionally so far succeeded as to subdue the morbid excitement down to that grade which is necessary to the restoration of the secreting and excreting functions, and the production of a salutary crisis. We sometimes observe a large or full depletion in a few hours afterwards followed by a general perspiration, and copious alvine evacuations. But this result should not be confidently calculated upon, even in the class of patients just mentioned, and least of all in fevers arising from infection

and mental anxiety, or during epidemics, however early in the stage of reaction it may be resorted to. Much discrimination is necessary, even in cases where the practice appears to be indicated, not to run a risk of mischief by having recourse to it.

131. When, in the progress of fevers, but more especially at their commencement, signs of local determination or of predominant vascular action appear in the head, lungs, or abdominal viscera, depletions, both local and general, are most requisite. If, however, these affections come on in advanced periods of the fever, although depletion to some extent is required, the existing states of vital power and action, and even of the blood itself, often forbid it to be practised nearly to the amount generally required in idiopathic inflammations, — unfavourable terminations or even gangrene rapidly supervening, owing to these states, upon a too free recourse to it; for it is not so much from excessive action, as from diminished power, and alterations of the circulating fluids, that these unfavourable results occur in the progress of fevers. The earlier, however, the predominant local disease or complications appear, the more energetically may bloodletting be employed.

132. *β.* The *circumstances* more especially requiring recourse to vascular depletions may be summed up as follows: — (*a*) Inordinate excitement, or irritation with rigidity of fibre, and general increase of the animal heat; — (*b*) When the patient is robust, plethoric, or young; the sanguiferous system being so surcharged as to prevent the free exercise of the functions; — (*c*) When the general reaction of the vascular system is such as to endanger vital parts, or too strong to allow a salutary or critical change, or so vehement or tumultuous as quickly to exhaust vital power; — and, (*d*) When the blood is determined to, or vascular action is inordinately increased in, an important organ. — In these *conditions* bloodletting is employed, with the following *intentions*: — *α.* To remove the excitement and irritation, and relax the exhaling and secreting surfaces and organs; — *β.* To diminish the load which oppresses the vascular system, congests it, or overpowers the organic nervous influence that actuates it; — *γ.* To reduce the excessive reaction, and thereby to guard important viscera, to prevent consequent exhaustion, and to favour the supervention of salutary evacuations; — *δ.* To remove or divert the increased impulse or action from important organs.

133. *γ.* There are certain considerations and symptoms *contra-indicating* bloodletting, that should not be overlooked. Some of these I have seen but too often neglected, even by old practitioners; and others so remarkably misinterpreted by them, as to have been their only reasons for having recourse to depletion, although actually the strongest indications against it. — A very frequent, soft, and open pulse seldom or never admits of depletion, for in such cases the tone of the vessels is insufficient to accommodate them to a diminution of their contents; consequently, remarkable sinking and depression, with increased rapidity of the circulation, &c., supervene. The pulse may be also open, soft, expansive, and tumultuous, indicating excessive action beyond vital power, as in certain forms of adynamic and malignant fevers attended by contamination of the circulating

fluid. In this state, the loss of even a very few ounces of blood will produce bad effects. Vascular depletion is seldom well borne in fever, when the pulse ranges so high as 110, and still more rarely if it reach 115 or 120, in adults. Irritable females, however, and those in the puerperal state, offer exceptions to this.

134. Great prostration of strength and of vital power; the supine posture; languor of the eyes; paleness or collapse of countenance; a lurid complexion; a dark or flabby state of the tongue, with indentations of the teeth on its edges, or dark mucous sordes on the tongue, gums, and teeth; great sadness and depression of spirits; low delirium; tremblings of the hands, and especially of the lower jaw; a feeble, small, and weak, or an open, compressible, and undulating pulse; a frequent and hurried respiration; incontinence of fæces or urine; coldness of the extremities, or of the ears or nose; coldness or rawness of the expired air; softness and flabbiness of the soft solids; and a dirty, muddy, lurid, or discoloured appearance of the integuments; are the strongest indications against any kind of depletion, and in all circumstances of fever.

135. In addition to these, the noxious nature of the exciting causes; their concentration, and their intense operation, as in the case of infectious effluvia; imperfect ventilation, &c.; the character of certain epidemics; the continued influence of the contaminated air, or of the infectious emanations that caused the fever; previous depression and insufficient nourishment; the presentment of an unfavourable issue, or mental distress and anxiety; the circumstance of the patient being treated in the midst of the malaria, or marshy exhalations, that caused the disease, or in an hospital, camp, house, or low street, in which infectious fever is prevalent; all militate against bloodletting, or indicate a necessity of caution in respect of it, according to the form which the disease assumes. — Vascular depletion also is not so well borne by persons living on a poor watery diet; nor by the studious and exhausted; nor by the fat, bloated, cachectic, and intemperate; nor by residents in low marshy districts; nor by those confined in close factories, or living in close or low apartments and streets; nor by persons passed fifty; as by those differently circumstanced. But the various species of fever furnish peculiar indications in favour of or against bloodletting that will be considered in their proper places.

136. *δ.* Of the repetition of bloodletting. — Previously to determining upon a second depletion, the effects both immediately and more remotely consequent upon the first, and the character of the disease, should be most carefully studied. It may happen that the first bleeding, although small, has produced fainting, followed by so strong reaction as to render a second or even a third full or moderate bleeding indispensable. This is chiefly observed when the first has been practised too early, or before the stage of reaction has been fully developed. If the fever is complicated, and the local affection presents much of the inflammatory character; if the patient has been relieved by the former bleeding; if the pulse remains good; if reaction, or determination to an important organ be diminished, the symptoms which indicated the first depletion still persisting

to a certain degree; we may proceed to a second, but always with circumspection. If, on the contrary, the pulse becomes weak, and the strength sinks, we never ought to repeat the bleeding. In all cases, the physician should attentively observe the pulse during the flow of blood, in order instantly to assure himself of the propriety of depletion: for if it become feeble and irregular, and the patient at the same time more distressed, the evacuation should be immediately stopped. The blood drawn in the first instance sometimes furnishes indications for or against the repetition of bloodletting; but such indications should seldom be acted upon alone. The inflammatory coat, and cupping of the coagulum, are favoured by cold, dry weather, by the puerperal states, by the rheumatic diathesis, and by the blood being taken in a full stream, and in a deep and narrow vessel. — But this condition, as well as a very loose or dissolved coagulum, or imperfect separation of it from the serum, and the other states of the fluid described in the article BLOOD (§ 78. *et seq.*), should be duly considered, in connection with the other phenomena, before they can be made the basis of curative indications. VAN ROTTERDAM justly states, that when the crust consists of a delicate bluish membrane, covering a greenish gelatinous matter, the crassamentum being livid, soft, and floating in a thick and greenish serum, a second bleeding will prove most mischievous; — and I may add, that least of all should depletion be repeated, in any mode, if the colouring matter be precipitated to the bottom of the weak crassamentum, and of a blackish or purplish colour.

137. *ε.* *Local bloodletting* is required chiefly in very young patients, or after general depletion, or in local determinations and complications, or in circumstances that render the propriety of bloodletting doubtful. It is most serviceable when the head is affected, and then either cupping or leeches may be employed, but preferably the former, when a quantity exceeding six ounces is to be taken away; and either mode may also be adopted when the viscera in the large cavities are affected. If leeches be employed late in fever, particularly in its low and complicated forms, care should be paid to the bleeding after their removal, as it is apt to continue, and is arrested with difficulty. *Dry cupping* is sometimes useful in states of internal congestion, when the detraction of blood can hardly be risked.

138. *ζ.* The question has been often agitated, *How late in fever should bloodletting be practised?* but it evidently cannot be answered by any absolute rule, or without reference to the *ensemble* of existing phenomena. In the cerebral and pulmonary complications, as well as in others in some cases, bloodletting, in one mode or other, may be employed until an advanced or critical period. But reaction having come on, and the indications for it being evident, the earlier in the disease it is resorted to the better. In the stage of crises, both vascular depletion and all perturbing means should be avoided. The indications already noticed respecting this remedy will assist the practitioner as to both the latest time of resorting to it, and the repetition of it; but in these matters, as in many besides, he must be guided chiefly by his pathological knowledge, and powers of practical observation and discrimination.

139. *b.* *Refrigerants*, internal and external, are of great service in moderating vascular excitement; and some of them produce this effect more than others, without lowering vital power. — *a.* The choice of *internal refrigerants* should depend upon the form fever assumes, and upon their especial action. In the early part, and more sthenic forms of excitement, sedative refrigerants should be selected, as the *nitrates of potash or soda* — the various *neutral salts*, the *mineral*, and *vegetable acids*. Several of these may be advantageously conjoined, as a solution of the *sulphate of magnesia*, with that of the *acetate of ammonia*; and other substances, also tending to promote the exhalations and secretions, may be added. In the far advanced stage of excitement, and in its more adynamic or low states, refrigerants which are more restorative and antiseptic — as *camphor* in small doses, the *hydrochlorate* and acetate of ammonia, the *spirit of nitric ether*, and the various *atherial preparations*, particularly *chloric ether* — are upon the whole to be preferred; and may be conjoined with numerous other substances, according to existing morbid conditions. The refrigerant effect of several of these is only relative to the state of action at the time, but it is not the less beneficial. Thus, in the low excitement characterising adynamic fevers, or when vascular action exceeds vital power, and the heat of surface is of a morbid kind, both the vascular action and the unnatural heat are best reduced by the more restorative refrigerants, as by camphor, the hydro-chlorate of ammonia, chloric ether, &c., all which may be given in conjunction (F. 431.). Much benefit will also result from a judicious choice of refrigerant beverages or drinks during the stage of excitement. A selection suitable to particular cases may be made from those prescribed in the APPENDIX. (See F. 592, 593, 594, 595. 915 and 916.)

140. *β.* *External refrigerants* are of great service, but they often require much discrimination. The patient, especially in warm weather, should be laid upon a hair mattress, covered only by a single sheet, and his surface sponged, in the more active states of febrile excitement, with cold spring water. If this be done frequently, as much benefit and much less fatigue will be experienced, than from the cold affusion, which, although more rapidly lowering the animal heat than it, hastens the return of the cutaneous reaction. If much determination to the head exist, the hair should be cut off, and *cold*, in various forms, as the *affusion* of a stream of *cold water*, evaporating lotions, &c., should be resorted to, the head being placed on a cool pillow. Formerly, there was much difficulty in regulating the temperature of the head; for, although one half of it was readily cooled by lotions, the other half was kept remarkably hot by the feather pillows in constant use. I frequently, therefore, placed under the pillow-case a folded piece of common floorcloth, which, by intervening pieces of linen, might be so managed as to carry off the excessive heat of the head, as rapidly or as slowly as could be desired. Pillows may now be filled with either air or cold water, and their temperature regulated according to circumstances.

141. In cases of determination to internal viscera, excepting to the head, the use of external refrigerants is more or less hazardous; and, if

the local complication be serious, and the general excitement of a low or adynamic form, it should be laid aside. But when this form of reaction is general, and not attended by excessive determination to, or congestion in, any of the thoracic or abdominal viscera, *tepid*, or *warm sponging* and *ablution*, will prove both useful and grateful. Whether cold, tepid, or warm sponging be adopted, the addition of bicarbonate of soda or of potash, or the bi-borate of soda, to the water thus used, will tend to relax the skin, and will cleanse it from the impurities which impede its functions. In cases accompanied by an acrid heat of surface, tepid sponging, or the tepid bath, medicated as just directed, will be advantageously followed by *frictions with sweet oil*, which, by relaxing the exhalants, will cool the surface.

142. *c. Antimonials* are amongst the most energetic *contra-stimulants* in fever; but they are not suited to all fevers, nor to all their stages. They are most serviceable in the more sthenic or inflammatory forms, in those arising from other causes than infection, in some epidemics more than others, and in the earlier periods. The best preparations are the true *James's powder* and the *potassio-tartrate*, the former of which may be conjoined with *calomel* and small doses of camphor, or with mild aperients; and the latter may be given in various saline solutions, or in the patient's common drink. Tartar emetic has been employed most largely in Italy to lower febrile excitement, but I believe that it will be found equally beneficial and less injurious to the digestive mucous surface when used in moderate doses. I have frequently given as much as three or four grains in the course of the day in solution; but from one to two grains has been equally serviceable. It is especially indicated when pulmonary affections supervene in the course of fever; but it should not be prescribed in low or adynamic fevers, even when thus complicated, unless with great caution, and in combinations hereafter to be noticed. A judicious use of either of these medicines early in the stage of active excitement, will often either entirely supersede depletions, or prevent the necessity of having recourse to those which are large.

143. *B. Inordinate depression of vascular action*, during the period of the disease which usually follows that of invasion, is very much less frequent than the states of excitement. It sometimes requires the most active means to remove it, but these means should have reference to the cause, and the various pathological states attending it. This condition generally arises from the intense impression of the exciting cause on the organic nervous influence, preventing thereby the evolution of vascular reaction; the stage of excitement either not following the earlier changes, or appearing in an irregular and imperfect manner. In such cases, which are most common in certain epidemics, and in some localities productive of the more concentrated states of malaria, there is generally more or less congestion of the large vessels, and parenchymatous viscera; and the vascular depression is dependent — 1st, upon lowered nervous influence; — 2dly, upon an overloaded or oppressed state of the circulating and vital organs — the state of *congestion* so strongly insisted upon by STAHL and his disciples, but which I have shown (§ 92.) not to be a primary cause, as believed by more recent writers. In

this case, the means advised for the stage of invasion (§ 122.) should be resorted to, especially the *heated air* or the *vapour bath*, and *warm baths*, followed by *frictions* of the surface. In some cases, especially when irregular or unavailing efforts at reaction are made, the abstraction of a few ounces of blood from a vein, whilst the patient is immersed in a warm bath, and frictions of the surface are being employed, will often assist in restoring circulation to the surface, and in removing the internal congestion. If the pulse rise during the flow of blood, a larger quantity than otherwise might be safe may be taken, or the operation may be repeated, according to the effects observed after the first evacuation. If a satisfactory result is not soon observed from these, a hot *turpentine epithem* should be placed over the epigastrium and abdomen, and covered over with oiled silk, or leather, so as to prevent evaporation; and be either kept there or renewed until *erubescence* of the surface is produced. In the more dangerous cases, a similar epithem may also be applied to the insides of the thighs. At the same time, moderate doses of *camphor* or *ammonia* may be given internally, in warm diluents, or small quantities of the *chlorate of potash*. Depressed vascular action, whether occurring in the early progress of the disease, or consequent upon some grade or other of excitement, being chiefly an effect of the change in the state of organic nervous power, although often associated with congestion at the commencement, and with vitiation of the circulating and secreted fluids in the latter stages, should be further combated by the measures which are required for the fulfilment of the next intention; an especial attention to these conditions being paid in the remarks about to be offered.

144. *C. To support organic nervous and vital power*, especially when associated with imperfect vascular reaction, or with a morbid state of the blood, or when proceeding from exhaustion, is of the greatest importance; but the circumstances in which the accomplishment of this intention becomes requisite, and the treatment most appropriate for it, in the various states of fever, are amongst the most difficult topics of practical medicine. In certain varieties, especially those that commence with low excitement or imperfect reaction, the debility is owing in great measure to *suppression of power* — to the overloaded state of the vascular system, consequent upon interrupted exhalation and secretion, preventing its free reaction upon its contents. In such, power is best restored by moderate vascular depletion, the pulse becoming more free and developed as the congestion and load are removed. It is in this class of cases that early evacuations are most requisite, as the best means of preserving vital power, and are the oftenest neglected; whilst in others, particularly those which are characterised by excessive action, although attended by loss of vascular tone and nervous power, or by a vitiated state of the blood, or both, depletions are inappropriate, and the most likely to be injuriously resorted to. In certain adynamic fevers, in which reaction assumes this latter form, and apparently indicates bloodletting rather than opposite means, if employed sufficiently early and with much circumspection, some advantage, or little mischief, may result from it, especially if the patient was

in health, well-fed, or at all plethoric, before the attack. But when the pulse is very quick, broad, or open, the vessel yielding on a gentle pressure of the finger, as well as before the impulse of the heart upon the column of blood in it, depletions should either not be attempted, or be accompanied with remedies which will restore nervous power. In general, however, they are in any mode hazardous in such cases; the febrile poison or cause having infected the organic nervous influence, and the vascular system, as well as its contents, and prostrated vital power in such a manner as to be roused only by tonics and restoratives. But even in these circumstances, stimulants should at first be cautiously used and judiciously selected; for a too early recourse to them, especially to such as are at all heating, may be very injurious. When this state of the circulation occurs late in the disease, or is consequent upon a more vigorous reaction, and an obviously vitiated state of the blood, the most energetic means of restoration are necessary.

145. Debility from *suppressed power* is frequent in the early periods of fever, when the brain and lungs are predominantly affected, and is best relieved by moderate depletions and derivatives. Care should be taken to distinguish this form of debility, as, whether occurring early or late, the use of stimulants would be more injurious than beneficial, unless in peculiar circumstances, and when these medicines are conjoined with other more appropriate means. The association of this state with vascular congestion, in these as well as in other cases, requires rather the treatment directed for depressed vascular action (§ 143.) than that for exhaustion.

146. It must be evident from the foregoing, therefore, that numerous circumstances must be duly considered before restoratives — either of a tonic or stimulant kind — should be resorted to in fevers. These circumstances furnish the true *indications* for the employment of them, and are chiefly the following: — *a.* The intense operation of the causes of infectious and epidemic fevers, these generally requiring, *ceteris paribus*, an earlier and more liberal use of restoratives than those which are sporadic; — *b.* The summer and autumnal seasons; — *c.* An age past the meridian; — *d.* Imperfect nourishment and clothing; the patient having lived chiefly on vegetables, or on fish, or salt provisions, or having been addicted to ardent spirits, or to sexual indulgences; — *e.* An intermittent, remittent, or low *type* of fever, or any of its *adynamic forms*, especially if uncomplicated with any inflammatory state; — *f.* The continued operation of the poisonous effluvia which caused the disease, as in low marshy situations, the close air of crowded hospitals, &c.; — *g.* Signs of real debility or of exhaustion, especially when attended by a moist or flabby tongue, by a very soft and quick pulse, the secretions not being suppressed; — *h.* An indifferent or apathetic state of mind, despair of recovery, mental depression, &c.; — and, *i.* The symptoms enumerated above as contra-indicating bloodletting (§ 133.). Besides these, there are numerous others, which appertain more especially to certain species and forms of fever, and which will be noticed hereafter. Various circumstances may, however, arise, which will render vascular depletions, and a recourse to tonics, and even to stimulants, nearly at the same

time, extremely proper. Remittents and intermittents, particularly in warm countries, and several complicated states of continued fever, often exemplify this.

147. *The selection of means* in order to support nervous and vital power must have reference to the cause and form of fever, and to existing pathological states and complications. In *endemic fevers*, the various preparations of *cinchona* and sulphate of *quinine* are upon the whole most appropriate. In those caused by *infection*, the same preparations with *camphor*, the chlorates, especially the *chlorates* of potash and soda, *serpentaria*, *arnica*, *camphor* with *opium*, *wine* given in *Seltzer water*, *yeast*, *carbonic acid*, various *tonic infusions* taken with the *citrate of ammonia* in a state of effervescence, *spirits of turpentine*, *pyroligneous acid*, *kréosote*, the *mineral acids* and *æthers*, especially the *hydrochloric* or *chloric*, and *chloric æther*; and in the complicated states of fever, especially external *derivatives*, *vesicatories*, *sinapisms*, *epithems* with warm turpentine, or liniments with this latter, and *camphor*, *capsicum*, &c., are the most efficient remedies. When the blood appears contaminated, or the excretions acid, offensive, and excoriating, combinations of tonics with antiseptics, as the decoction of *cinchona* with the chlorate of potash — a combination which I have used for many years with much success — or with *chloric acid* and *chloric æther*; the *pyroligneous acid* with *kréosote*; *spirits of turpentine*, &c.; and these, or similar substances, administered in *enemata*; are the most to be depended upon. But the appropriation of these and of other remedies to the particular forms and states of fever, is more fully shown in the sequel.

148. *D. The promotion of the exhalations, secretions, and excretions, by emetics, purgatives, diaphoretics, and diuretics*, is a most requisite intention in the cure of every type and form of fever. By a judicious selection of means belonging to these classes of remedies, adapted to existing pathological conditions, vascular action may be developed when it is low or suppressed, or moderated when it is excessive; nervous power may be relieved when it is oppressed, or supported when it is exhausted; and the circulating fluid may be preserved in a state of comparative purity, or relieved from the contamination it may have experienced in the course of the disease.

149. *a. Emetics* were formerly more employed in fever than at present. — SYDENHAM, STOLL, and many others, prescribed them very generally; but the recent views as to the seat of fever in the brain, and digestive mucous surface, have tended to bring them into disuse. In the early stages of the simple and sporadic forms of fever, they are often of great benefit, especially in arresting them, as advised above (§ 121, 122.), or in developing imperfect action. They are seldom productive of much service after the excitement has become fully established or stationary, and should not be employed in the cerebral complication, or when tenderness or pain are felt in the abdomen, especially at the epigastric region. When prescribed thus early, they are calculated to prevent congestions of the lungs and liver, and even to remove them at their commencement. SYDENHAM, from a fear of their effects upon the brain, seldom prescribed them until bloodletting was premised, and thereby lost much of the benefit they are

calculated to afford, inasmuch as the period at which bloodletting could be advantageous, was more advanced than that in which emetics are most serviceable. Ipecacuanha is, upon the whole, the best substance that can be used. Tartar emetic is not so safe, if there be tendency to the gastric complication, or in low infectious forms of the disease. Some authors have recommended emetics at a late period; but I have had but little experience of them later in fever than I have advised them. In the early stages I have both frequently prescribed them, and seen them prescribed, with benefit. They may, however, prove beneficial in more advanced periods, especially in the bronchial complication, and to answer particular purposes; but they should be conjoined with such other substances as will assist them in answering the especial intention with which they are directed.

150. *b. Purgatives* are the most generally prescribed medicines in fever, in this country; and are at least amongst the most useful when judiciously selected. *Calomel* early in the disease, in conjunction with *James's powder*, and in the adynamic states with *camphor*, &c.—*Jalap* with *cream of tartar*, in sporadic cases—*the mild neutral salts*, or the more *cathartic salts* in mild doses, in similar circumstances,—*rhubarb* in nearly all fevers, variously combined,—*spirits of turpentine* with castor or olive oil, &c. when the head is much affected, and in certain states of the abdominal viscera; and various other mild aperients, as *mannu*, *tamarinds*, *prunes*, &c., with the *citrates*, *tartrates*, &c.; are the most serviceable. *The phosphate of soda*, or any of the strong *neutral salts*, either alone and in small doses, or with diaphoretics and diuretics, will frequently produce both refrigerant and evacuant effects. They are indicated chiefly during the stages of excitement, more especially in sporadic and endemic fevers.

151. In general, the purgatives used in fevers should be mild, and such as are not calculated to irritate or inflame the digestive mucous surface. They should be employed with the intention—1st, of simply removing mucous sordes and accumulations from the *prima via*;—2dly, of promoting the secreting and excreting functions of the collatitious viscera, and of the intestinal surface;—and, 3dly, of thereby unloading the vascular system of a part of the effete materials conveyed into it, and liable to accumulate in, and contaminate, the blood. They should rarely or never be prescribed with a view of deriving the circulation from other parts to the digestive canal; for, in fevers, irritants of any kind acting upon this part will often react upon the brain and liver; with the exception of the purgatives just enumerated. If oils be employed, especial care should be taken that they are quite fresh, otherwise they may occasion great danger. In pulmonary complications, the addition of the potassio-tartrate of antimony in small doses, or of ipecacuanha, to the purgatives, will be useful, and will promote their operation. In advanced stages, the utmost discrimination is necessary in the selection of purgatives, and more especially if we dread the presence of disease of the mucous follicles. In these, doses of rhubarb sufficient to evacuate freely the bowels, with the hydrargyrum cum creta, camphor, and ipecacuanha, are most beneficial. This lesion is com-

monly connected with, if it be not caused by, the injurious remora of sordes or morbid secretions in the canal, and by a vitiated state of the blood; the aperients or purgatives selected should, therefore, not merely be mild, but possess tonic and antiseptic properties, or be conjoined with such substances, especially camphor, cinchona, sulphate of potash, the chlorates, or kréosote.

152. *c. Diaphoretics* should be prescribed with strict reference to the existing degree of excitement; for if the vascular action mount above a certain pitch, the cutaneous exhalation cannot be procured until it is reduced; and if it sink too low, the perspiration will either be interrupted, or become partial or clammy. In the stage of excitement, therefore, depletions and refrigerants are the most efficacious diaphoretics; or such substances as relax the skin by acting on the digestive mucous surface, as calomel with antimony, and in some forms of fever especially, with opium; or ipecacuanha with nitre and opium, &c. During this period, the more cooling diaphoretics should be selected, especially those mentioned under the head of refrigerants, (§ 139.), and emollients and relaxants, will often very materially aid their operation, especially if gastric and intestinal irritation be present. Whenever vascular action, or vital power, particularly the latter, sinks materially, the warm or stimulating diaphoretics, as camphor, serpentaria, ammonia, arnica, &c., should be preferred, and be combined with tonic infusions, &c., according to the circumstances of particular cases and existing pathological states.

153. *d. Diuretics* are upon the whole less requisite in fevers, than the preceding; but they are often useful adjuncts to tonics, diaphoretics, or even to the milder purgatives. The ætherial preparations, especially the spirits of nitric æther, citric acid, and the citrates, the tartrates, and most of the neutral salts, and nearly all the refrigerants (139.), may be thus employed. They are indicated more especially in the pulmonary, cerebral, and hepatic complications of fever; those of an antiphlogistic kind being the most appropriate.

154. *e. Mercurials* are often necessary in fevers, especially calomel, blue pill, and the hydrargyrum cum creta. *Calomel* is of great service as a deobstruent purgative, in fevers arising from endemic causes, especially when the liver becomes obstructed; in conjunction with opium, after bleeding, in the gastric and other complications; and with camphor and opium, in certain malignant states, which will be particularly noticed. *Hydrargyrum cum creta* is most useful with ipecacuanha and rhubarb, or with camphor and opium, in the intestinal affections occurring in the progress of the disease. Of the use of mercurial frictions in continued fevers I have not had much experience; but in periodic fevers, when the liver has become enlarged, I have directed them with advantage; using either the ointment with camphor, or the mercurial liniment with the compound camphor liniment, or one of those in the Appendix (P. 306. 311.). Mercury pushed so far as to affect the mouth or to produce salivation, has been considered both a prophylactic and a cure for fever. I have tried to affect the system in the most malignant forms of fever in warm climates, without succeeding; and where I have succeeded, there was every reason to believe that recovery

would have taken place nevertheless. In some complicated states of fever in this country I have given very large doses of calomel and camphor with opium every four or six hours, with success; and although recovery has taken place, as frequently without the mouth having been affected, as otherwise, I have generally considered the latter a favourable occurrence. This treatment was introduced by me about fifteen years ago, and was then resorted to in many cases in a public institution: it was taught in my lectures, and published in several periodicals ten or twelve years since. The circumstances in which it is calculated to succeed will be pointed out hereafter. That mercury possesses no prophylactic influence against fevers, has been satisfactorily shown by several able writers, and proved by my own experience. A person, whose mouth was affected for the cure of syphilis, was seized with malignant remittent fever, in Africa, in 1817, and came under my care soon after the attack. He died a few days afterwards; the most active treatment having failed in developing vascular reaction, and in supporting the vital powers. A nearly similar case is mentioned by Dr. GRAVES, in his excellent lectures. I believe, however, that instances in which *salivation* has followed a mercurial treatment of fever, without recovery having taken place, are very rare.

155. *E. It is often necessary to remove local congestions, determinations of blood, or predominant states of vascular action, or other disease of particular viscera, during the progress of fever, and thus to protect important viscera from injury during the febrile action.*—*a.* One of the most dangerous and most frequent complications—one which does not limit itself to any particular type or form of fever, although more frequent in some localities than in others, and in some epidemics—is *predominant affection of the digestive mucous surface*, particularly of the lower part of the ilium and cæcum. This condition is more particularly noticed hereafter, with reference to its early occurrence; when it forms the mucous gastric and intestinal fevers of authors. It is chiefly to its occurrence in the advanced stages that I shall here advert. Notwithstanding the erroneous views of BROUSSAIS and his followers as to this point of pathology, we are indebted to them for the great attention which has been paid to it in recent times. Unfortunately, lesions in the small intestines may proceed to a fatal issue in fevers, without any evident sign of their existence. Those symptoms, nevertheless, which are most frequently observed, as well as those which are occasionally connected with them, should receive due attention. When, therefore, pain or tenderness are felt in the abdomen or epigastrium on pressure, with tension and burning heat, a loaded tongue with red point and edges, a soft and very quick pulse, from twelve to twenty leeches should be applied; and after the bites have bled sufficiently, a warm turpentine epithem or fomentation in the same situation will prove of great benefit. This epithem has been very frequently employed by me, since 1820, in the complicated states of fever, in both public and private practice, and has been publicly recommended by me for them on several occasions soon after that time.

156. *a.* If this complication appear early in fever, a repetition of these means will often be neces-

sary; and, if the bowels be not sufficiently free, or if the evacuations be acrid and offensive, laxatives, especially rhubarb with the hydrargyrum cum creta, ipecacuanha, &c., and emollients or demulcents, will be necessary. If it occur very late in fever, and be attended with much depression, or with *diarrhœa*, small but frequent doses of the hydrargyrum cum creta, with camphor, ipecacuanha, and opium, ought to be given, the above epithem being also resorted to; and, if these fail, the chlorates, particularly the chlorates of potash or of lime, should be prescribed, with the preparations of cinchona, or of tormentilla; or the treatment advised for the *Asthenic Forms of DYSENTERY* (§ 88, *et seq.*) may be employed. In these latter cases the affection of the mucous follicles is either consequent upon, or coëtaneous with, contamination of the circulating and secreted fluids; therefore the chlorates, cinchona with hydrochloric acid, chloric æther and opium, camphor in large doses, kresote, and other tonic and stimulating antiseptics, are especially indicated. If dark grumous or bloody stools, and more particularly if large *discharges of blood* take place, turpentine should be administered by the mouth, and in demulcent enemata, it being the most efficacious means we possess in such circumstances, as well as when flatulent distension of the abdomen supervenes. Ulceration of the follicular glands, and softening and even sloughing of the mucous surface of the bowels, may take place in the latter stages; and, although these lesions are often preceded by the symptoms just noticed (§ 155.), and attended by evacuations indicating their occurrence, no very conclusive evidence of their existence may be observed, unless they terminate in perforation and peritonitis. This is more especially the case, when the abdominal symptoms are marked by severe cerebral affection. But ulceration may especially take place in this insidious manner also when the sensibilities are not thus obscured, and even during the periods of decline and convalescence.—These more extreme changes in the internal surface of the bowels, can be met only in the manner just advised, the medicines being exhibited both by the mouth and in enemata; and by the means recommended in similar states occurring during DYSENTERY (§ 89.).—If *peritonitis* consequent upon ulceration and perforation supervene, terebinthinate epithems, or sinapisms, and large doses of opium, as advised by Dr. GRAVES and Dr. STOKES, or of camphor and opium, are the most rational means. The administration of other medicines by the mouth or by injections, or, indeed, the ingestion of any substance whatever, may increase the mischief, by its passing through the perforation, which may possibly be repaired, if the actions of the bowels be restrained by the remedies just advised; the natural processes which sometimes take place in such cases, being thereby favoured. The application even of leeches may be injurious, particularly if this occurrence take place late in, or during adynamic states of, fever, by depressing the powers of life too low for the exertion of the usual processes of repair.

157. *β.* The occurrence of *diarrhœa*, of a mild character, the stools being feculent and not remarkably unhealthy, should not be interfered with, more especially at a critical period of the dis-

ease. But when the symptoms of inordinate vascular determination are present, the evacuations being watery, offensive, or otherwise morbid, small doses of hydrargyrum cum creta and DOVER'S powder should be given every four or five hours; and, if these fail, and more especially if the type of fever be low, the stage far advanced, and vital power depressed by the evacuation, the more active means just mentioned (§ 157.) should be administered. This complication is more common, and more apt to assume a dangerous form, in some localities than in others. Thus it is more frequent and severe in Paris than in London, and in London than in Edinburgh, probably owing to the water in common use in these cities.

158. γ . When *flatulent distension* of the abdomen comes on in any of the forms of fever, but more particularly in adynamic states, PIERRY advises that an elastic tube should be introduced into the rectum in order to carry off the flatus. I am, however, not sure that the discharge of it in this manner is so beneficial as may be supposed; and I am confident, that at the period of the disease when this is a troublesome symptom, the internal surface of the bowel will be readily injured, owing to its tender and almost softened state, even by the incautious introduction of a clyster-pipe. I have, since 1820, recommended and employed the spirits of turpentine, in cases of this kind, — by the mouth, in several forms (F. 216.), in enemata (F. 150, 151.), and in warm epithems and fomentations placed upon the abdomen. This substance is especially indicated where, with the abdominal distension, and intestinal affection, there is also delirium or coma; and is equally beneficial in a relaxed, as in a constipated state of the bowels; for, by modifying the dose and the combination, it will increase or restrain their actions, according as either effect is desired. In a remarkably dangerous, and indeed hopeless, case of this description, which I attended in 1822, with Mr. BUSHELL of Crawford Street, this medicine was resorted to with instant benefit and ultimate success; and, although I have met, both previously and subsequently to this date, with numerous instances, in public and private practice, where it has proved equally beneficial, I refer to this in preference, because it is amongst the earliest cases of the kind, of which I can find the notes, where I employed this medicine in consultation with another practitioner, — the fact thus not resting merely upon the testimony of an observer, who may be supposed to be over-partial to a medicine which he was the chief means of bringing into general use (see my *Memoirs on the Action and Use of Terebinthinate Remedies in various Diseases, in the Lond. Med. and Phys. Journ.* for July and August, 1821.), but also upon that of an equally competent observer. A nearly similar instance to that now referred to is added by Dr. GRAVES (*Lond. Med. and Surg. Journ.* vol. ii. p. 781.).

159. The nature and treatment of the complications of fever with intestinal disease have not always been well understood; for, as they have too frequently been considered as merely inflammatory, and not as consequences of the pathological states explained above, so have they been viewed as contra-indicating the exhibition even of mild purgatives. — This, however, is not the case;

inasmuch as they may not only be occasioned by the insufficient use or neglect of these medicines early in the disease; but also aggravated by the same cause, at a later period. The septic and irritating effects of the morbid secretions and excretions poured into the alimentary canal, and even from its own surface, during the course of adynamic fevers, when its mucous membrane possesses its minimum of tone and vital resistance, require both that the intestinal contents should not be allowed to accumulate and remain long in contact with it, and that they should be rendered less injurious by dilution and the exhibition of antiseptic substances, — indications of which both reason and experience have shown the propriety and success.

160. *b.* The complications of fever with severe lesions of the respiratory functions and structures are more frequent, and often occur earlier, than generally supposed. — The influence of early impairment of these functions in the production of the consecutive phenomena of fever should of itself attract a particular attention to them during the progress of the disease. We shall generally find that, in proportion as the causes of fever act intensely upon the lungs, and impede the changes of the blood in them, the more severe and complicated will be the form of the disease, and the more disposed will this organ be to experience either manifest or concealed disorder, generally consisting of a peculiar congestive form of bronchitis, or of congestion of the lungs and bronchial lining, or of determination to these parts, or of asthenic or nervous pneumonia, passing into condensation of portions of the organ, in the lower types of fever; or of peripneumony or more purely inflammatory states of both the lungs and pleura, in the more inflammatory varieties. There are also other circumstances which should influence the treatment of these complications, viz. — *a.* Their greater frequency in the low adynamic fevers, than in the sthenic; in the continued, than in the periodic types; and in some epidemics, seasons, and localities, than in others; — *b.* The particular stage of the fever in which they appear; — *c.* The part they seem to act in superinducing further complications, especially cerebral and hepatic affections; — and *d.* Their particular form and character in relation to general vascular action and nervous power. It must be evident that, inasmuch as this complication may supervene, and proceed to a fatal length, without detection, especially when the brain is much affected, an attentive inquiry after it should be made by means of auscultation, through the progress of the disease, and even during convalescence.

161. *a.* In cases where the local affection, as well as the general disease, evince most of the inflammatory characters, *general or local depletions*, according to the circumstances of the case, are especially indicated. Of the latter, *cupping* is the most useful, especially between the shoulders, — and if leeches be applied, the glasses may be placed over the bites. In the adynamic states, local depletions only are admissible; and if leeches be used, attention should be paid to the bleeding afterwards. If further depletion cannot be ventured upon, *dry cupping* on the back or chest will sometimes be serviceable. Great advantage will also accrue from resorting to external derivation or revulsion, after sufficient depletions have been practised. The repeated application of blisters,

so as to produce merely a rubefacient effect; or of sinapisms; frictions with irritating liniments (F. 299, 300.), especially with capsicum, croton oil, &c.; and stinging with nettles; are frequently beneficial. But I have found, in numerous cases, since 1821, of both common and eruptive fevers, where these means have failed, that warm terebinthinate epithems, placed over the chest or epigastrium, or even upon the insides of the thighs, and retained or repeated until erubescence and burning heat were caused, have produced decided benefit. Such instances have occurred where I have met with other practitioners, amongst whom I may mention Mr. FAXON, Mr. BARNWELL, Mr. PAINTER, Mr. BRYANT, Mr. BYAM, Dr. T. WILLIAMS, and Mr. LEESE, who have witnessed with myself the efficacy of this application.

162. *β. Antimonials*, especially the tartar emetic solution, have been much employed in this complication; but the caution already offered respecting their use (§ 142.), particularly in the low forms of fever, should not be overlooked. The doses of the potassio-tartrate of antimony ought not to exceed the quantity advised above. When judiciously employed, and following moderate depletions, it is productive of great benefit, and very frequently prevents the necessity of recurring to bloodletting. In some of the states of predominant pulmonary affection, where, although occurring early in the disease, vascular depletion can hardly be ventured upon, this substance, either alone, or with camphor and small doses of squills and opium, will often prove efficacious. In such low forms of the complication, especially when supervening late in fever, even tartar emetic may not be either beneficial or indicated. In these, the external derivatives just mentioned; ipecacuanha with camphor and opium, or also with squills; the decoction of senega, and other medicines advised in the *Asthenic Form of BRONCHITIS* (79. 84.); will prove most serviceable. It will sometimes become a question, whether or not wine and the more active tonics and stimulants, sometimes required at an advanced stage of adynamic fevers, should ever be administered when complicated with nervous or asthenic bronchitis or pneumonia. To this I would answer, that, having resorted to the means already advised, or merely to dry cupping, the external applications and the internal medicines just insisted upon, without benefit, vascular depletion not being further admissible, the administration of appropriate stimulants and tonics should not be longer delayed, and more especially in an advanced stage of fever, the external means being repeated and assiduously persisted in. Before, however, wine and the more heating stimulants and tonics be resorted to, the effects of camphor in full doses, or of ammonia, with opium, &c., should be fully tried. If the bronchi be loaded with accumulated mucus, and the respiratory functions thereby obviously impaired, the exhibition of an emetic (F. 198. 402.), or repetitions of it, will be serviceable, however late in the disease.

163. *γ.* The treatment just advised is also applicable to the more rare complication with *pleuritis*. Vascular depletions are more generally required, and may be carried to a somewhat greater extent in it, than in associated bronchial and pneumonic affections. Full doses of calomel, James's powder, and opium, are particularly indicated;

and if the mouth become affected, the occurrence may be considered favourable. The external remedies should be strenuously enforced, particularly the turpentine epithem, on the outside of which a piece of soft leather or oiled silk may be laid, in order to prevent evaporation. The tartar emetic solution should also be prescribed; and the more largely, the more manifestly sthenic or inflammatory the fever and local affection; in order to economise the loss of blood.

164. *c.* The *affections of the cerebral functions* owing to their nature, often present more prominent characters in fevers, and hence attach to themselves greater importance than they are actually entitled to. Even in cases where they have been most remarkable, the *post mortem* examination has not disclosed any lesion sufficient to account for them. The circumstance of their being more frequently caused by the state of organic nervous influence in the encephalon, and by morbid changes in the blood, and of their being often consequent upon affections of the respiratory functions and of the digestive mucous surface, has been too generally overlooked; and a treatment has consequently been adopted, more calculated to interfere with the salutary efforts of nature, than to remove morbid conditions which have actually existed. If we analyse those cases which present, in the common estimation, very prominent lesions of the cerebro-spinal functions, and compare these lesions — whether of mental manifestation or of voluntary power — with those evinced by the other organs or systems, — with the functions of digestion, assimilation, circulation (comprising the changes affected by respiration on the blood), secretion, and excretion — in what will the predominance of cerebral disorder be found to consist? and, still more, to what organ or system will the balance of morbid action incline? Keeping, therefore, this inference in view, that prominent symptoms, especially those connected with the sensitive functions, do not always prove, or truly indicate, the amount of lesion, or even its seat in the part disturbed, the cerebral complications of fever should receive a due but not an exclusive attention, even when most predominant. In proof of this position, I can appeal to no very limited experience, and to those who, like myself, have witnessed the worst forms of typhus fever, as they occurred in various parts of France and Germany soon after the peace, whether or not death was caused more by the cerebral than by the other changes, judging from an intimate analysis of the symptoms in the latter stages, and of the morbid appearances. Indeed, in many instances, the lesions of other organs were individually greater than those found within the cranium.

165. In cases of fever attended by very marked determination of blood to the head, or by vascular action increased to an inflammatory state, or by severe cerebral symptoms at advanced stages of the disease, *vascular depletions*; full doses of calomel, with purgatives, or followed by them, especially by Formula 216., and enemata (F. 140. 150.); and cold applied to the head, particularly the cold affusion on it, the rest of the body being kept moderately warm, or revulsants being applied to the lower extremities; should be promptly resorted to. Bloodlettings ought not, however, to be too implicitly confided in, for they will never of themselves remove this complication. No advan-

tage will accrue from opening the temporal artery or jugular vein, above that derived from bleeding from the arm; and even this will not be frequently requisite; the more especially as an equal or even greater benefit, at a less waste of blood, will result from cupping largely on the nape or over the mastoid processes, or from leeches in the latter situation and occiput. Both bleeding and the cold affusion on the head may be carried to an injurious length, especially if it be attempted to remove, or materially to benefit, within an inadequately short time, this complication; many of the phenomena of which are dependent upon, and inseparable from, the fever, and to be removed only with it. Let not, therefore, this or any other treatment be mischievously persisted in, with the mistaken view that it can accomplish what the nature of the disease renders impossible; but at the same time, let it not be insufficiently employed. Purgatives, especially those with calomel, with James's powder, or other antimonials, should follow early depletions, particularly if this complication occurs early in the fever; and at later periods the calomel may be given with opium, every four or six hours, the bowels freely opened, and derivatives applied to the insides of the thighs or calves of the legs. As to the treatment of COMA and DELIRIUM in fever, it is unnecessary to add any thing to what I have advanced in those articles, and at other places in this. It should, however, be recollected, that other complications may coexist with predominant cerebral affection, particularly in adynamic fevers; and if this affection be very severe, or consist of delirium or coma, and more especially if it depend upon a morbid state of the blood, these complications may be thereby masked, and proceed to a fatal height before they are detected. This we have seen to be the case as respects the lungs and intestines, and it is not less so as regards the liver and spleen. Nor should the readiness with which sphacelation occurs, either from the pressure of the body, or from excoriating discharges, and inattention to cleanliness, and to the preservation of a dry state of the linen, or from blisters or injuries, be overlooked; for an early inquiry after the first indications of this occurrence will often prevent much trouble, suffering, and danger.

166. *F.* The regimen and management of patients in fever are much more essential to recovery than is sometimes supposed. Not only are the purity, dryness, and rapid renewal of the air deserving of attention, but also its temperature, which ought to be regulated, as well as the quantity of the bed-clothes, according to the states of vascular action and vital power. The patient should be screened from too free a current, particularly of cool air, and especially in fevers of low excitement, as the pulmonary and, indeed, other complications may be induced by this circumstance. When excitement is fully developed, the air should be cool, and the clothes light; but in other conditions, especially when the temperature of the body does not rise above natural or is depressed below it, proportionately increased warmth is necessary, in respect of both the air and the quantity of bed-clothes. The room also should be darkened, all noise excluded, and mental excitement or irritation carefully avoided. The mouth and gums ought to be

washed from time to time, and the linen changed very frequently; the surface of the body being sponged with simple or medicated water, of a temperature in relation to the forms of fever, as stated above (§ 140.). All the evacuations ought to be passed in the bed-pan without leaving the supine posture; and if they take place involuntarily or unconsciously, oiled silk should be placed next the bed, and folded sheets underneath the patient. Care must be taken that retention of urine or over-distension of the bladder does not occur, without being detected at once and remedied. The accounts of the nurse must not be trusted to in this, more than in other matters, but the state of the abdomen above the pubes carefully examined. If pressure cause excoriations, or threaten sloughing, measures should be immediately taken to prevent further mischief. The part may be washed, as Dr. GRAVES advises, with a solution of ten to fifteen grains of nitrate of silver in an ounce of water, or with a weak solution of the super-acetate of lead in spirits of turpentine; or with this latter and dilute pyrologneous acid; or it may be covered by defensive plasters. If sloughing occur, carrot poultices copiously sprinkled with the chlorates, particularly of lime, or with spirits of turpentine, or with kréosote, must be employed; or poultices with bark, to which either of these may be added; and pressure removed from the part and its immediate vicinity by air-pillows, or by the use of Dr. ARNOLD'S hydrostatic bed. But these unpleasant occurrences should be prevented, where the appearance of the soft solids and the prostration of the patient indicate a disposition to them, by having early recourse to these latter means, and by supporting vital power by the means appropriate to existing pathological states.

167. *G.* The food and drink in fevers should be varied with the existing states of vascular action and power. In periodic fevers, light food may be allowed in proportion as the apyrexial period is complete. But in continued fevers, particularly during the early stages, and whilst excitement continues, no food beyond thin water gruel, fresh whey, and orangeade or lemonade, should be given. The best drinks during excitement are those prescribed in the APPENDIX (F. 592. *et seq.*), or any of the mineral acids in sugared water, and flavoured by lemon peel, or weak black tea, according as they may be congruous with the medicines prescribed internally. Thus, care should be taken not to allow the patient any of the mineral acids, when calomel, or any of the other preparations of mercury, is being taken. But when vascular reaction is low or imperfect, and vital power considerably depressed, or when the pulse is very rapid, tumultuous, and soft, Seltzer or soda water with old wine, hock, or weak punch, or wine whey, spruce beer, brisk bottled stout or brisk bottled beer, &c., according to the peculiarities of the case and the previous habits of the patient, may be allowed. If coma be present, green tea is one of the best beverages that can be allowed; and if the powers of life be very depressed, it may be made into a weak punch; the patient also being often roused by talking to him on lively interesting topics. He may be allowed oranges, grapes, or lemons sweetened with sugar, particularly when the mouth is foul and dry; but care should be taken that neither the pulp nor the stones are

swallowed. These will often both refresh and feed the patient as much as is necessary until the decline of the disease. If the fever be prolonged, or of a slow nervous character, very light nourishment may be allowed as the excitement subsides, such as roasted apples, jellies, in some cases asses' milk, sago, arrow root, tapioca, wine whey, chicken or mutton broth, weak beef tea, &c.

168. *II. Convalescence* from fevers requires the utmost discrimination of the physician, and yet both the patient and his friends are but too eager to supersede his functions. The ill consequences of mismanagement in this period are chiefly — 1st, Relapse; — 2dly, Inflammatory affections of the lungs, bowels, or brain; — 3dly, Dropsical effusions; — and, 4thly, Mental alienation. These are usually caused — *a.* by the patient getting up too early from bed; — *b.* by errors in diet; — *c.* by too early exposure to the weather, to the sun's rays, to cold, malaria, &c.; — *d.* by mental excitement or irritation; — and, *e.* by premature exertion of the physical powers. Convalescence is prolonged and difficult, and the consequent risk of some one of the ill effects of mismanagement supervening proportionately great — *a.* when the fever has been unusually severe; — *b.* when it has been very promptly and actively treated at its commencement, and either quickly subdued, or thereby rendered of short duration; — *c.* when it has slowly subsided without any regular crisis; — *d.* when it has been complicated in the severer forms stated above.

169. *I. Relapses*, as well as inflammatory or other affections of the principal viscera, are most frequently caused by getting about too soon, and by indulgence of the appetites, particularly that for food, which very generally requires restraint at this period. When the disease has been shortened by large bloodlettings, these, or other ill effects, as mental alienation in persons predisposed to it, are very apt to occur. The greater is the necessity, therefore, to place the patient upon the strictest diet and regimen during convalescence. At the same time he should not be kept too low, either in respect of food or medicine; or otherwise anæmia, dropsy, mental disorder, chronic debility, and rheumatism, &c. may be thereby produced. Change of air, sea-voyaging, and travelling, with due precaution against cold or wet, will particularly assist recovery. If either of these cannot be adopted, the use of gentle tonics, especially when the situation is not remarkably healthy; and strict attention to the bowels, and indeed to all the secretions and excretions; are particularly necessary. The patient should not be in too great haste to remove the hair after fever, or to have it cut too close; and he should be particularly careful not to expose his head to the sun's rays. The return to his occupations — whether mental or physical — as well as to his usual food, ought to be gradual. As the cuticle and hair generally fall off after severe fevers, warm or tepid baths, when convalescence is far advanced, will promote the patient's comfort.

170. If, notwithstanding these precautions, a relapse takes place, the treatment should proceed according to the principles developed in this article with reference to its cause, the progress it has made, the state of action, and of power, &c. The fact of the greatest proportion of cases of this kind being occasioned by errors in diet

should not be overlooked. Hence the great success ascribed by the older writers to an emetic in such circumstances. Therefore, after the action of an emetic, the bowels also ought to be freely opened by a mild purgative, the operation of which may be promoted by enemata; and the treatment, in other respects, should proceed according to the type and form the disease assumes, and the stage at which our assistance is required. If a relapse is merely threatened, or if the symptoms characterising its invasion be present, the remedies just mentioned are especially indicated, with the other means above advised (§ 121, 122.) in this period. (See the art. *DEBILITY*, § 36. 43. 45. 46. for still more particular directions as to the management of *CONVALESCENCE* and as to the measures that ought to be adopted.)

XI. INTERMITTENT FEVER. SYN. — Διαλειπόντες πυρετοι, Hippocrates and Galen; *Anetus*, Young and Good; *Kalte Fieber*, *wechelfieber*, Germ.; *Puludal Fever*, *Periodic Fever*, *Ague*. 171. DEFIN. — *The febrile phenomena running their course rapidly, observing a certain succession, usually terminating in crises, and returning after regular apyrexial intervals.*

172. Intermittents have been divided by modern writers — into the *quotidian*, *tertian*, *quartan*, &c.; into *vernal* and *autumnal*, — into *regular*, *erratic*, and *anomalous*, — into *simple*, *complicated*, and *masked* (*FOURIER*, *VAIDY*, &c.). But in addition to these TYPES, which have reference merely to the intervals between the accessions of the paroxysms, agues assume certain FORMS or CHARACTERS, which are still more important than they are, in a practical point of view. These have been variously distinguished by writers. *J. P. FRANK* has arranged them into the *nervous*, the *gastric*, and *inflammatory*, the second and third of these, in being *complicated*, often assuming a remittent type. *J. FRANK* has divided them into 1st, the *evident*, and 2nd, the *masked*; the former being — *a. benign*; *b. malignant*; *c. regular*; and, *d. irregular*. *M. PINEL* has classed them

into *inflammatory, gastric, mucous, adynamic, and ataxic*; — M. BOISSEAU, into *benign, pernicious, or complicated, and erratic, anomalous, or masked*; — and the Author, into — *a. the simple, or uncomplicated*; *β. the inflammatory*; *γ. the adynamic*; *δ. the complicated*; and, *ε. the anomalous, or masked*. — I shall follow the same arrangement here.

173. — *i. Simple Ague* — *Mild, uncomplicated, or benign Intermittent* — appears after a longer or shorter interval from the time when the morbid impression was made by its cause upon the system. During this *formative* or *premonitory* stage, symptoms of disorder may be more or less manifest; but they are often very slight, or hardly discernible, until shortly before the paroxysm, which may occur suddenly or unexpectedly, with the usual *invading* symptoms (§ 35.). The *premonitory* phenomena are essentially the same in ague as have been described (§ 33.); but frequently, during the few days immediately preceding the full development of the fit, slight fever appears, and returns about mid-day or a little before; consisting of accelerated pulse, white tongue, thirst, lassitude, and pains in the back and loins, loss of appetite, high-coloured urine, &c.

174. *a. The fully developed paroxysm* commences with a creeping chilliness along the spine, with languor or a sense of fatigue, paleness and slight collapse of countenance, lividity of the nails, and a feeling of universal coldness. The temperature of the surface is reduced; the skin is dry and rough, sometimes with livid patches, or spots, especially on the extremities; shiverings, tremblings, or rigors occur; and the teeth chatter. Sighing, oppression, or anxiety at the præcordia, yawning, stretchings, difficult or forced respiration, occasionally cough, and nausea, are also present. The patient complains of a constrictive pain in the head and temples; of aching of the back and loins; and of clamminess and a disagreeable taste in the mouth. The tongue is white or loaded; the appetite lost; the urine limpid, sometimes pale, and voided often; and the bowels are generally constipated. Sickness and bilious vomiting sometimes supervene and hasten the next period; the pulse is constricted, small, weak, and often accelerated; and the mental powers are weakened, or overpowered. — Such is the *cold stage*, which answers to the period of *invasion* described above (§ 35.).

175. *b. These symptoms*, having continued from half an hour to three, very rarely to four, hours, are followed by transient flushes of heat, at first alternating with rigors; by restlessness; great heat of surface; flushings and turgescence of the countenance and skin; rending headach and throbbing of the temples; by a full, strong, and free pulse; high-coloured and scanty urine, intense thirst, and most of the symptoms characterising the period of *excitement* (§ 36.), with the first part of which especially, this, the *hot stage*, corresponds.

176. *c. After a time* varying from two to eight hours, but most frequently three or four, perspiration breaks out over the forehead and breast, increases rapidly, extends over the whole body, and soon becomes profuse. All the symptoms now subside quickly; the urine being more abundant and depositing a lateritious sediment; the bowels being more readily acted upon, and the mind

more composed. A sense of exhaustion only now remains, and the patient often falls asleep; and the paroxysm is at an end. This, the *sweating stage*, corresponds with the *periods of crises and decline* (§ 40, 41.). The whole *duration* of the fit varies from four to sixteen hours, the common length of it being about six or seven.

177. *A. The Types and Intermissions.* — The paroxysm, having terminated more or less completely in health, some degree of lassitude and debility usually remaining, is renewed after an interval, the duration of which constitutes the *type* of ague, — after twenty-four hours, in the *quotidian*; after forty-eight hours, in the *tertian*; and after seventy-two hours, in the *quartan* types. The most common of these is the tertian, which is considered the primary type of fever. These form the primary and regular types of intermittents; but there are others which are *irregular*, as the double, triple, and reduplicating tertian; the double, the triple, and reduplicating quartan, &c. Of these, the *double tertian* is the most common, and differs from the quotidian only in having, on alternate days, fits corresponding in severity, character, and duration. The *triple tertian* has two fits on one day, and one the next. A *duplicated tertian* has two paroxysms in alternate days, with one whole day of intermission. A *double quartan* has a fit on one day, a slighter fit the next, and a complete intermission on the third day; the paroxysms returning in a similar manner on the fourth and fifth. A *triple quartan* has a paroxysm on each day — on the two usual days of intermission; but, as in the case of the double tertian, the fit of each differs in character, and period of accession, so that the one returning every fourth day is alike. The *duplicated quartan* has two paroxysms on one day, with two whole days of intermission. Besides these, intervals of four, five, six, seven, or eight days may occur, or even longer periods, constituting *erratic* or *atypic* forms of ague; and may be caused by treatment, by atmospheric vicissitudes, or states of the digestive organs; but they are comparatively rare.

178. *a. The quotidian* usually begins in the morning, and continues the longest; having the shortest *intermission*, or period between the termination of one fit, and the commencement of the next. — *b. The tertian* usually appears about noon; the duration of the fit being about seven or eight hours, but that of its hot stage being often the longest. — *c. The quartan* commences in the afternoon (from two to five), and has the longest cold stage, and the shortest paroxysm. — *d. The tertian* is the most common, the regular quotidian the least so. — *e. Agues* are most prevalent in spring and autumn; tertians and quotidians in spring, and in adults of a sanguineous or bilious temperament; and quartans in autumn, in very young persons, in females, and in the lymphatic temperament. Tertians are the mildest and the shortest in duration; and sometimes disappear of themselves. Quartans are removed with greatest difficulty, particularly in autumn; and they occasionally continue till the following spring.

179. *B. The longer the apyrexial interval*, the more complete is the restoration to health; but during this period, or *intermission*, the patient often complains of weakness, of heaviness or pain of the head, of a sense of cold, want of appetite, &c.;

many of the symptoms stated above, as indicating the *formative* period of fever (§ 33.), being present. Indeed, the interval in every respect corresponds with this period. When the ague continues some time, although it may not change its type or form, as it is then prone to do, especially in warm climates, the patient becomes weaker, loses flesh, has a sallow hue, and experiences obstructions or enlargements of the spleen, liver, mesenteric glands, &c., with a deranged state of the secretions and excretions; the disease passing into the complicated states (§ 183.), or terminating as will appear hereafter (§ 189.).

180. C. The *conversion* of one type of ague into another often occurs: tertians and quartans changing to quotidians, or to double or triple tertians and quartans, especially when they become aggravated; and quotidians into tertians when they are somewhat ameliorated. Agues, particularly quotidians, may also be converted into remittents, or even into the continued type, by the constant operation of the exciting causes, or by other powerful determining influences; but they often assume a complicated or an irregular form in the course of transition. When the fits of a quotidian, or of a double tertian, or of a triple tertian, approach each other so closely that the one is hardly finished before the next commences, the fever has been called *sub-intrans*, or *sub-intrans*; and differs but little from a remittent type, excepting that the cold and sweating stages may be somewhat more marked in the former.

181. ii. *Inflammatory Ague*.—Intermittents with more or less of inflammatory excitement have been described by SYDENHAM, PRINGLE, HUXHAM, SELLE, FIZEAU, BOISSEAU, &c. Mr. ANNESLEY and the Author have shown their frequency in warm climates, especially during the cold seasons, in elevated situations; and in persons of a previously healthy constitution. They are characterised by very severe rigors in the cold stage, followed by vomitings and intense vascular reaction; unquenchable thirst; by severe and rendering headach, sometimes with delirium; by great heat and by turgescence of the countenance and of the whole surface. The reaction during the hot stage is generally attended, particularly in plethoric persons, by marked determination to, and vascular turgescence of, particular viscera, according to accessory or determining causes. The organs which thus evince a predominance of vascular action, are, the encephalon; the liver and stomach, especially in warm climates, and in autumn in cold countries; the lungs and bronchi, in some instances; and the uterine organs, in rare cases.—This form generally assumes a tertian or quotidian type; is easily removed if actively treated, owing to its common occurrence in sound constitutions; but it rapidly passes into organic change, or into the remittent or continued type, in hot climates, when neglected or improperly treated.

182. iii. *Ague with oppressed Power*, or partaking more or less of an *adynamic* character, is often met with in Europeans who have resided long in hot miasmatic countries; in debilitated persons living in low, marshy, and moist countries; and in the intemperate; but it rarely occurs in these in an uncomplicated state. Whilst vascular reaction and vital power rise above the standard presented by *simple ague*, in the *inflammatory*

form; they sink more or less below it, in the *adynamic*.—The cold stage is often attended, in this latter, by general tremblings, rather than by strong rigors; and is followed by nausea and vomiting; developing a burning or pungent heat of the skin, which is dry, and occasionally somewhat sallow. The pulse is very quick; the tongue loaded, and red at the edges; and the epigastrium tender and oppressed. This state nearly approaches the *gastric variety* of Continental writers. More frequently, however, this form commences with horripilations, seldom amounting to trembling or rigors; often with nausea and vomiting; fullness at the epigastrium, and headach. To these succeed increased heat, alternating at first with chills; a quick, oppressed, but not hard or full pulse; somnolency, and imperfectly developed and hot and sweating stages.—Thirst is not much increased; the heat is moderate; the skin is sallow, yellowish, or lurid; the urine citron coloured; and the subsequent perspiration is scanty, or offensive.—This form usually assumes a quotidian, double tertian, or triple quartan type; more rarely tertian; and sometimes erratic. It commences also irregularly, either early in the morning, or in the evening, or at night. The *intervals* are attended by more or less disorder; by an unhealthy appearance of the surface, a loaded tongue, and morbid excretions. The lower grades of ague are more frequently complicated (§ 183.) than simple; or, if the latter, they soon superinduce congestions, obstructions, and organic lesions of important viscera, most frequently of the stomach and bowels, of the spleen, liver, mesenteric glands and pancreas.

183. iv. *Complicated Ague*—*Intermittent perniciosa*, of the French—*Intermittentes comitate*, of TORTI,—the *Malignant*, of some writers—is very frequent in warm climates, and in marshy districts in the south of Europe; and is sometimes met with in parts of this country. It usually presents the preceding form as respects the states of vascular action and power, but it may assume more or less of the inflammatory character, particularly in the early paroxysms. It often has less perfect intermissions than the foregoing forms, especially after two or three paroxysms; is generally quotidian, double tertian, or triple quartan; and frequently passes into a remittent or nearly continued type, especially in Europeans who have resided long in hot countries, and in the intemperate. It appears in two ways;—*a.* primarily in a faulty constitution, or in persons with previous disorder of some important viscus,—and, *b.* as an advanced grade of either of the preceding forms. The most frequent complications are with diseases of—*a.* the digestive and biliary organs and spleen; *b.* of the thoracic viscera; *γ.* of the cerebro-spinal functions; and, *δ.* of other parts.

184. A. *With disease of the abdominal organs*, ague presents diversified symptoms, according to the viscus especially affected.—*a.* If the *stomach* be particularly diseased, severe, burning pain at the epigastrium, with tenderness, distension, nausea, and vomitings, which are increased by whatever is taken into the stomach; distressing flatulency; dry or red tongue; high-coloured and scanty urine; sallow or depressed countenance; yellow streaks around the mouth; imperfectly developed hot stage, with a sharp, quick, and contracted

pulse; pungent heat on the trunk, with little alteration or even depression of it in the extremities; intense thirst, hiccup, and headach or delirium, are commonly present. — *b.* If the *liver* is principally affected, fulness, pain, oppression, or tension at the epigastrium, right hypochondrium, and right shoulder; oppressed breathing; bilious vomiting; diarrhoea, or a dysenteric and morbid state of the stools, which are sometimes black or bloody; a jaundiced, sallow, lurid, and harsh appearance of the surface; and the other symptoms just enumerated; are complained of. — *c.* If the *bowels* are chiefly disordered, the fever assumes a dysenteric character, the evacuations being very morbid; sickness and vomiting are less urgent, or are altogether absent; and the hot and sweating stages are imperfectly formed. — *d.* If the *spleen* be diseased, more or less enlargement is very evident in the region of it; extending into the epigastrium, and over a great part of the abdomen; most of the other phenomena being also present. — These complications may co-exist, or one or two of them may predominate; but they seldom continue long without assuming still more dangerous features; and the patient sometimes dies in the cold stage. The heat of surface often passes from an acid or pungent state, to a clammy or raw condition, as the paroxysm subsides; and the coldness or lividity of the extremities frequently continues through its imperfectly developed stages — syncope, great debility, quick, small, and weak pulse; a dry, brown, red, or raw state of the tongue; constant thirst; anxiety and oppression at the præcordia; and lastly, delirium, coma, or death taking place.

185. *B.* The *pulmonary complication* is much less common than the abdominal; but I believe that congestion of the *bronchi* and *lungs* obtains to a greater or less extent in most forms of ague, especially in the cold stage; and that, in the more severe states, a sub-inflammatory condition, or active congestion, often exists, although in a form that can be recognised only by the aid of the stethoscope. Dr. STOKES has adverted to this in his able paper on the treatment of ague. But in ordinary circumstances, the respiratory organs merely participate with other viscera of the large cavities in the congestion characterising the cold stage. If, however, symptoms of inflammatory, sub-inflammatory, or congestive disorder of these organs continue throughout the hot stage, the ague may be justly considered as complicated with such disorder. The symptoms, even when the pulmonary affection is most severe, are not always very decided, unless the pleura be implicated, which is seldom the case. Those of catarrh, or of bronchitis, are the most common; but the substance of the lungs may be seriously affected without much cough being present; the respiration being only short, quick, or laboured. Particular attention is therefore necessary when this symptom is complained of. The *paroxysm* of ague in this complication is usually *quotidian*, or *double tertian*; and, in *character*, it may be more or less inflammatory, and but rarely adynamic, unless it has continued for some time.

186. *C.* The *cerebral complication* is seldom observed in the early course of ague; but it often supervenes on the adynamic and the inflammatory forms, and upon that attended by the complications already noticed, especially the abdominal.

According to the particular character which the cerebral complication during the paroxysm presents, it has been denominated the *delirious*, *apoplectic*, *lethargic*, *comatose*, *soporose*, *epileptic*, *convulsive*, or *paralytic*, these affections occasionally occurring — the delirious and comatose being the most frequent, the epileptic and paralytic much more rare. TORTI, STARCK, WERLHOF, and BAILLY, have adduced cases of the apoplectic complication; but it is rather a termination of the disease — recovery from it being rare. The convulsive state occurs chiefly in children, as observed by STOLL, especially in warm countries. These states seldom occur in this country, unless towards the close of a neglected or improperly treated ague, when the functions and state of the more important excreting organs have been overlooked. They are, however, more common in the south of Europe, as shown by the numerous cases adduced in the works of GROTANELLI, BAILLY, and others.

187. *D.* Besides the above, several other complications have been noticed by writers: of these the most remarkable are, the *rheumatic* and *arthritic*, the *neuralgic*, the *asthmatic*, the *nephritic*, and *uterine*. But although instances rarely occur in which these affections accompany a fully developed paroxysm of ague, they present themselves rather as masked intermittents, or without a clearly defined fit.

188. *v.* *Masked Ague — Simulating Intermittent — Febres Intermittentes larvata*, of foreign writers — may assume most diversified forms; or rather, during seasons in which intermittents are very prevalent or epidemic, numerous affections, especially those of the nervous system — as *neuralgia*, *rheumatalgia*, *arthritic rheumatism*, and *sciatica*; *gout*; *headach* and *hemicrania*; *amaurosis*; *toothach*; *otalgia*; *catarrh* and *asthma*; *palpitations*; *painful affection of the spleen*, *neuralgia*, *hysteria*; *singultus*; *gastralgia*, or *enteralgia*, or *colic*; *epistaxis*; various disorders of the stomach; and *paralysis* — may put on an intermittent type. Of these, the rheumatic and neuralgic are the most common; and as they frequently are occasioned by the same causes as produce ague, acting in a less intense mode, the circumstance of their intermittent form cannot be a matter of surprise. A case of intermittent flatulency lately occurred to me, the quantity of flatus eructated daily from noon to three or four o'clock being enormous, the patient continuing to belch without intermission. The type of masked ague is generally quotidian, double tertian, or tertian, and sometimes quartan or double quartan. As in other forms, it is most common in spring and autumn, especially the former, and when easterly winds prevail; and is usually attended by more or less disorder of the digestive, biliary, and excreting organs — a successful treatment mainly depending upon attention to this circumstance.

189. *vi.* CONSEQUENCES AND TERMINATIONS OF AGUES. — *A.* The *Effects* of ague depend upon — *a.* the previous health and strength of the patient; — *b.* the intensity of the causes, and the duration of their action; — *c.* the continuance of the disease; — *d.* the treatment adopted; — and, *e.* the other circumstances noticed above (§ 47). Intermittents seldom continue long, even in the simple form, or return frequently, without materially

impairing the vital energy and vascular tone of the viscera of the large cavities, especially those of the abdomen. Hence arise — 1st, the complications described above; — 2dly, remittent or continued fevers, with more or less affection of particular organs, or of the circulating and secreted fluids; — 3dly, inflammations or structural change of internal viscera, superseding the periodic seizures; — 4thly, dropsical effusions; — 5thly, chronic dysentery and diarrhoea; — and, 6thly, a fatal issue, chiefly in the cold stage, owing to insurmountable congestion of the lungs, heart, liver, and spleen, or to rupture of this latter organ.

190. The congestions of these viscera, in connection with impaired organic nervous power, more especially of the liver and spleen, give rise, by frequent repetition, to enlargements, to a torpid state of the former, and consequently to engorgements of the portal vessels and of the hepatic ducts; to imperfect secretion and assimilation of the chyle absorbed and passed into the mesenteric veins; to obstructions of the mesenteric glands; to obstructed circulation and its consequences, through the veins contributing to form the portal circulation; and ultimately to an unnatural state of the blood, and structural lesions of the digestive mucous surface, and of the large secreting and excreting glands. Hence old and complicated agues are accompanied with a sallow, sunk or bloated, and œdematous countenance; pale lips; foul, loaded tongue; yellowish, foul, or lurid skin; fulness, distension, or tenderness at the epigastrium, both hypochondria, and over the abdomen; pain and aching between or under the shoulders, and in the loins; clay-coloured, or dark, watery, offensive, and otherwise morbid stools, the bowels being more or less disordered; dark-coloured and scanty urine; great debility and dyspnoea; and a weak, irregular, and frequent pulse. If rupture of the spleen occur, acute pain is suddenly felt in the splenic region; with diffused fulness, pain, and tenderness of the abdomen; small frequent pulse, cold extremities, syncope, &c.

191. *B. Appearances in Fatal Cases.* — Death may take place either from overpowering congestions in the cold stage, or from rupture of the spleen; but it most frequently results from the superinduced disease of internal viscera, in connection with exhausted organic nervous power, and sometimes with a morbid state of the circulating fluids, particularly in the adynamic and complicated forms. The chief lesions are seated in the liver, spleen, digestive mucous surface, and lungs. — *a.* The *liver* is often enlarged; its consistence being either increased or diminished; tubercular or purulent formations being, moreover, dispersed through its substance. Increased consistence or density, softening, purulent or tubercular formations, &c. may also exist separately, or in various combinations. Engorgement of the vessels with dark blood; distension of the hepatic ducts and gall-bladder, with a dark or greenish black, thick, and viscid bile; thickening and injection of the ducts and gall-bladder, &c.; are often observed in connection with other lesions, but more especially with enlargement and softening of the substance of the viscus. — *b.* The *spleen* is often remarkably enlarged. MORAGNI and GROTTANELLI found it to weigh eight pounds. In some localities, it occasionally reaches an enor-

mous size. On the Gold Coast of Africa it has been found double this weight in Europeans. I saw a case in which it was nearly eleven pounds. Its envelope sometimes presents appearances of chronic inflammation — is injected, thickened, and almost cartilaginous. Its consistence internally is rarely increased; but is most frequently diminished; its structure being friable, oftener almost diffuent, or consisting of a greyish black semifluid substance, traversed by greyish fibrous shreds or fibres, and containing a sanguineous fluid of a purplish hue, or resembling wine lees. Instances have also occurred where adhesions have formed between the spleen and stomach, and between the spleen and colon in others; and the thick black blood of this viscus has been thus discharged into the digestive canal by ulceration, the matters passed from the bowels or thrown off the stomach presenting a blackish appearance (MORELLI, GASTÉ, BAILLY). — *c.* The *digestive mucous surface* is, in various parts — in the ilium, the cæcum, colon, stomach, duodenum, and œsophagus — more or less altered; often softened; injected with dark blood in patches or spots; and occasionally ecchymosed. The mucous follicles are frequently enlarged or inflamed in various parts. *Ulceration* is seldom observed, unless the disease has been complicated with diarrhoea or dysentery; and then this lesion, with thickening and softening of the coats of the bowels, especially of the cæcum and large bowels, and peritoneal injection, is generally observed. — *d.* The *mesenteric glands* are sometimes enlarged, and present signs of obstruction or of chronic inflammation; more especially when lesions of the digestive canal are very remarkable. — *e.* The *pancreas* is occasionally enlarged, in some instances so as to obstruct by its pressure the common bile-duct. — *f.* The *lungs* are sometimes congested; but seldom otherwise changed, unless pulmonary complications have existed, when similar lesions to those described above (§ 53.) are observed. — *g.* The *brain* and *its membranes* are not often much altered, unless in the comparatively rare cases in which coma has attended the fit; or apoplexy, or convulsions, or paralysis, has occurred in it; when congestion, injection of the pia mater, effusions of serum between the membranes, or in the ventricles, are the usual appearances. — *h.* *Dropsical effusions*, especially in the peritoneal cavity, and cellular tissue; a pale, flaccid, or softened state of the structure of the *heart*; and more or less discolouration of a yellowish, or lurid, or dirty hue; are sometimes also observed, particularly in the more adynamic or protracted cases.

192. vii. PROGNOSIS. — It is evident that an opinion as to the result of ague should depend especially upon the form and pathological condition in which it presents itself. As to these, enough has been advanced to enable the reader to form his own opinion. But in the adynamic and complicated forms especially, and in protracted cases, the diagnosis should be more or less unfavourable, or at least very guarded. The circumstance, also, that even in more favourable states of the disease, a very dangerous complication, or structural change, may occur, ought not to be overlooked, — apoplexy, coma, paralysis, fatal congestions of abdominal or thoracic viscera, or rupture of the spleen, may supervene. The epidemic prevalence of the disease, and more particularly the influence

of the locality, should be taken into consideration. In some situations, as in this country, ague is a comparatively mild disease; whilst in others, as in some parts of Italy, Austria, Hungary, Holland, low warm countries near the sea coast, &c. they are very serious maladies.

193. viii. **DIAGNOSIS.**—Ague may almost insensibly pass into *remittents*, especially when it assumes the quotidian, double tertian, or triple quartan types, or the adynamic and complicated forms. But in the latter there is no complete apyrexia, and the cold and sweating stages exist very imperfectly. *Hectic fever* may be mistaken for either of these types. But in *hectic* the pulse is always accelerated in the intervals, whilst in ague it falls to a natural frequency. The febrile paroxysm of *hectic* commences in the afternoon, and the sweating stage is of long duration; in *quotidians*, it begins earlier, its first stage is more severe, and its last is shorter, than in *hectic*. In ague the countenance is sallow, and the skin muddy or discoloured; in *hectic* the former is flushed, and the latter clear.

194. ix. **CAUSES.**—*A. Remote Causes.*—*a.* The predisposing causes of ague are, whatever depresses the physical and mental powers, more especially the causes fully described in the article on the *Causation of Disease* (§ 23. 27. 30. 33. and 35.).—*b.* The exciting causes are chiefly, if not solely, exhalations from stagnant water, or from marshy or clayey soils — from the various sources pointed out in the article on *ENDEMIC INFLUENCES* (§ 5. *et. seq.*). Some authors, as M. BOISSEAU and Dr. GOOD, state that agues may arise from other causes than from malaria. M. BROUSSAIS believes cold and moisture sufficient to occasion them; and M. VAIDY supposes that they may be produced by the influence of the mind and by irritation. Dr. GOOD and Mr. COOPER refer to the rare occurrence of ague in London from the commencement of the present century to 1822 or 1823, and to the frequency of the disease since this time, as a proof of other causes than malaria being in operation. But as respects London and its vicinity, changes have taken place sufficient to explain the circumstance. The streets have been Macadamised, constantly watered, and covered by a wet clayey mud; the soil surrounding the metropolis has been turned up for the purposes of building, &c. to a much greater extent since that period than formerly; and the muddy and marshy banks of the river have been unusually disturbed and inundated by the swell from the paddles of numerous steam-vessels. It should also be recollected, that the morbid impression may have been made upon the system many days or weeks before some determining or accessory cause—as exposure to cold, errors in diet, &c.—has occurred to bring it into action; and that without such occurrence, no effect might have followed the impression produced by the specific cause of the disease. Besides, after an attack of ague, very slight causes—as cold and moisture, painful injuries; improper diet, indigestions; north-east or easterly winds, &c.—will bring it back after months or even years have elapsed; the fully developed disease leaving the frame remarkably liable to be affected by the diffusion in the air of the smallest proportion of marshy effluvia. That agues may be caused by *infection*, has been believed by WERLHOF, CLEHORN, MARX, FORDYCE, KOR-

TUM, AMELUNG, AUDOUARD, and BAILLY; and instances have been adduced by them in support of the opinion. Dr. BROWN states, that he has met with cases which have led him to suspect that such was the fact. The *epidemic prevalence* of agues is, however, a better established fact, and has been admitted by most writers; the circumstances concurring to cause it being noticed in the article on *EPIDEMICS*.

195. *B. The proximate Cause or Nature of Agues.*—*a.* WILLIS attributed agues to a periodic fermentation in the blood; F. DELEBOË to the absorption of an acid fluid from the pancreas; and BORRELLI to irritation of the nerves, by an acrimony of their fluids. TORTI had recourse to something out of each of these three doctrines. BOERHAAVE and STOLL came nearer the truth, in viewing them as an affection of the nerves that admitted of no further explanation. SELLE and J. P. FRANK considered them to result from a peculiar irritation of the nervous system, and more especially of the nerves of the digestive organs. Dr. REIL, and M. ROCHE have entered into long and intricate explanations of the periodicity of the morbid action: the former imputing it to the intermittent character of all the organic and nutritive functions; the latter to the periodicity of the exciting cause, and to a disposition of the organisation to repeat the phenomena, it has several times experienced. M. BROUSSAIS attributed intermittents, as well as other fevers, to inflammatory action in the digestive mucous surface; and modifications of the doctrine have been offered by some who profess to belong to the same school—inflammatory irritation in some part of the digestive, or even of any of the abdominal organs, having been assigned by BOISSEAU, MONGELLAZ, &c. M. BAILLY, taking into consideration the circumstance of the localities of agues being those in which epizooties most frequently occur; and observing that, whilst the latter is always continued, the former is periodic, although the causes are manifestly the same; has come to the conclusion that the intermittent action is owing to the periodical change from the vertical to the horizontal position, which man only experiences. All these hypothesis, however, fail of fully explaining not merely the periodicity of the several states of ague, but also their difference of type. Those who espouse the doctrine as to the origin of intermittents in inflammation of some part of the digestive organs, are met by the fact urged by TOMMASINI and others, that true inflammation is not periodic, but continued. Whilst some endeavour to get rid of the difficulty by giving to the morbid action the name of inflammatory irritation. If, by this latter term, be meant a lower or slighter grade of increased vascular action of a part causing irritation of its nerves, a sort of amalgamation of the inflammatory and of the nervous doctrines is manifestly attempted—more or less of either being assumed, as the circumstances of particular forms of the disease may seem to require. The facts of M. MONGELLAZ as to the intermittent character of some forms of inflammation; and that recorded by Dr. ELLIOTSON, in which the bites of leeches became irritable and inflamed during a fit of ague; certainly do not prove the cause of ague to be inflammation, but merely what *a priori* reasoning, and a full recognition of the phenomena connected with the disease, might suggest; namely, that

either pre-existing or superinduced inflammation, if it be not sufficiently intense to supersede the intermittent type, will be aggravated during the paroxysm, especially the hot stage of it.

196. *b.* From attentive observation of the disease in localities the most fertile in its cause, I conclude—(*a.*) That paludal exhalations act in the manner already stated (§ 95.), and especially affect the nervous system of organic life;—(*b.*) That consequently the organs, which are especially actuated by this system, experience the chief effects of the morbid action; the functions of circulation, calorification, digestion, secretion, assimilation, and excretion, evincing the principal disorder, and the organs performing these functions the chief lesions in protracted, or fatal cases, as shown by the appearances described above (§ 191.);—(*c.*) That where, owing to the speciality of the exciting cause, and the intensity or continuance of its operation, its peculiar impression is fully made upon the organic nervous system, either pre-existing, or superinduced disease, inflammatory or even structural, if existing in a slight degree, or in a chronic form, will not supersede the periodic or intermittent type; but if such disease be acute or active, or associated with high irritability of fibre and vascular plethora, the type will be either continued or remittent, or change from the intermittent to either of these types;—(*d.*) That a similar conversion of type will result from contamination of the circulating and secreted fluids when it reaches a considerable height;—(*e.*) That in localities productive of malaria, the slighter diseases, especially those consisting chiefly of disordered function, or of altered sensibility, assume more or less of the intermittent type; only the most acute maladies, or those of altered structure, or attended by contamination of the blood, assuming a purely continued course;—(*f.*) After viewing the effects of malaria arising from the various sources pointed out in the article on ENDEMIC INFLUENCES (§ 5.), on the human frame, in the various epochs of existence; after considering the nature of the agents by which such effects may be counteracted, or removed; and after the experience of the primary and consecutive action of this particular cause upon my own system; I believe that it has a primary, specific, and uniform tendency to impair the energy of all the vital manifestations;—(*g.*) That the morbid impression having been made by it, and the formative changes having reached that pitch necessary to the production of the cold stage, the consecutive alterations proceed in the manner stated above (§ 101.), but much more rapidly and imperfectly, and in a way insufficient to efface the primary morbid impression made by the cause upon the organic nervous system; consequently the morbid state of this system is little affected by the successive changes characterising the paroxysm; and continuing the same after, as it was before the fit, is equally efficient in operating a return, after an interval of varying but of short duration, of the same succession of phenomena.

197. From this last inference, and from previous observations, it will appear, that each paroxysm is a complete febrile seizure, the successive and critical changes of which are insufficient in most instances for the restoration of health; that the disorder remaining after the subsidence of the fit is in every respect similar to that characterising

the formative or premonitory stage of fevers generally; and that it is necessary to the cure of the disease, that it should be treated in a nearly similar manner. This view is supported by the fact of relapses of continued fevers being common, when their duration is shortened by an active or very depletory treatment at their commencement. As to the periodicity of the return, or the relapse, of the febrile paroxysm in ague, it seems to be the consequence of the specific nature of the exciting cause, of the morbid impression made by it upon the organic nervous system; and of the continuance of this impression, or rather of the morbid state it occasions; for, as long as the morbid condition of this system is uneffaced by treatment, change of air, or by the full evolution of critical changes, it operates a return of the febrile paroxysm after an interval which may be prolonged or shortened by the state of vital power, and peculiarity of temperament or diathesis. As to any further explanation of the matter, I can add nothing to what is given in the article DISEASE (§ 155—157.).

198. *c.* The consecutive changes, and the low or complicated forms of ague, are manifest consequences of repeated seizures, or returns of the disease, in connection with predisposition, and with the intensity and continued operation of the cause. Owing to the impaired tonicity of the vessels, consequent upon depressed vital power, and to the frequent returns or severity of the cold stage, congestions, and subsequently torpor, obstruction, and organic change, of internal viscera, often take place, the large vessels becoming engorged, and the cavities of the heart itself sometimes softened, or distended and enlarged.—The changes observed in the digestive mucous surface are chiefly attributable to the same causes, and to the morbid condition of the biliary and pancreatic secretions. The low or adynamic forms are evidently results of the intensity of the cause in relation to predisposition and the state of system—of the continued operation of the cause, as when the patient cannot be removed from the locality productive of the malaria—of complications supervening in the course of the disease—and of changes in the circulating and secreted fluids.

199. *x.* TREATMENT.—Ague is treated with comparative ease and success, when the patient is removed into a pure air, and when it is neither complicated nor of a low grade. If removal is impracticable, it is often very difficult to manage, and dangerous as respects its consequences or sequelæ, although an unfavourable result may be long deferred.—The treatment, however, in either case, naturally divides itself into that applicable—*a.* to the paroxysm,—*b.* to the interval,—and, *c.* to the effects often consequent upon repeated attacks.

200. *A.* During the paroxysm.—The principal intentions that should be kept in view in the treatment of the fit, are—1st, to guard important viscera from injurious congestions during the cold stage; 2dly, to protect internal organs from the effects of excessive or inflammatory reaction in the hot stage; and, 3dly, to promote an abundant perspiration in the sweating stage, whereby the vascular system and the internal viscera may be relieved.

201. *a.* Treatment of simple ague.—The means advised by STOLL are here generally sufficient.

He employed warm diaphoretics, and external warmth, in the cold stage; refrigerants during the hot stage, and bloodletting if the patient was plethoric; and diluents and diaphoretics in the sweating stage. In some cases, a warm emetic (F. 198. 402.), administered at the commencement of the cold stage, is of essential service, especially when the biliary secretion requires to be promoted. — *Emetics* at the beginning of the fit have been strongly recommended by DE BOURGES, CLEGHORN, HUXHAM, MURRAY, CULLEN, TRNKA, OTTO, and THOMSON; but, although they may be serviceable in any of the forms of the disease, it is chiefly in the simple ague that they are unattended by any risk. They are contra-indicated by tenderness in the epigastrium or hypochondria; but in other circumstances they usually shorten the cold stage, and render the paroxysm milder. In slight attacks, when no particular viscus is predominantly affected, and the patient is neither very plethoric, nor much debilitated, and the disease has not been of long continuance, little further than diluents and diaphoretics, to promote the sweating stage, is necessary, until the intermission; when the usual means to arrest the disease are to be employed.

202. *b.* In the *more inflammatory form*, and in plethoric or aëthletic persons, especially in spring, *bloodletting*, general or local, or both, is necessary; if determinations to the lungs, head, or liver be remarkable, it should not be dispensed with; and still more especially if the paroxysms be prolonged and the apyrexia incomplete, — as these circumstances indicate the supervention of visceral inflammation. In these cases, the depletion may be practised in the hot stage, especially at its commencement, and when important parts are threatened by the severity of reaction; although in some instances it is better deferred until the interval, when the state of disorder and the effects of the evacuation may be more justly estimated, than during the tumult of reaction. Dr. MACKINTOSH, however, advises it to be resorted to in the cold stage; and in cases of the kind now being considered, or when congestion is great, in plethoric persons, it may be safely and beneficially practised. But in ordinary circumstances, or in the lower forms of the disease, I believe it to be a hazardous remedy in this particular stage. This opinion is substantially the same as that which Dr. W. STOKES has stated, after the full trial which he and Mr. GILL gave the practice. Cooling diaphoretics and diluents with diuretics, especially the potassio-tartrate of antimony, nitrate of potash, liquor ammoniæ acetatis, &c. are all the additional means usually required.

203. *c.* In the *low or adynamic form of ague*, a warm emetic (F. 198. 402.) should be given only at the commencement of the cold stage, and when indications of inflammatory action in the stomach or liver are absent. — *Warm diaphoretics* and antispasmodics in this stage, the *warm bath* followed by frictions of the surface and of the extremities, and the *vapour bath*, often shorten the hot stage, and give rise to a profuse and salutary perspiration. In several countries, the vapour bath at the beginning of the fit constitutes the chief, and almost the only, remedy against the disease; the copious perspiration following it, removing internal congestions and proving a perfect crisis. — If the paroxysm be attended by great fullness, and

tenderness at the epigastrium and hypochondria, *local depletions* should be resorted to in a decided manner, and *hot fomentations* afterwards applied. Where this practice has been already employed; or where the states of vascular action and vital power contra-indicate it, — which, however, will seldom be the case as long as the disease retains its periodic type; or even immediately after local depletions; a *mustard poultice*, or the *warm turpentine epithem*, should be placed over the stomach and abdomen, and retained or renewed until it cannot be longer endured, or until a copious perspiration is thereby produced; the latter application especially causing an abundant and salutary sweat. During the course of the paroxysm, *diaphoretics* should be freely administered with small or moderate doses of *opium*; camphor, ammonia, ather, warm wine whey, &c. may be also used with this intention. If great irritability of the stomach be present, the external means just advised will relieve it; or a large dose of *calomel* with *opium*, or with *camphor*, also, will have the effect.

204. *d.* The *paroxysm of complicated ague* is often irregular, the hot and sweating stages imperfect, and the intermissions incomplete, the disease assuming the characters commonly called *sub-entrant* (§ 180.). The cold stage is also frequently severe or protracted. In these, particularly at the commencement, the *warm* or *vapour bath* is a valuable remedy; especially in the lower and more congestive forms. If the complication be of an inflammatory nature; and if the lungs, liver, stomach, or head, be predominantly affected, general or local depletions, or both, should not be dispensed with. The circumstance of the hot stage being imperfectly developed, is no proof that internal inflammation or structural change may not be present; but is the strongest evidence of the existence either of these, or of congestion, and the most conclusive argument for vascular depletions and the external applications mentioned above (§ 203.). If inflammatory excitement be developed within the head, during the fit; or if delirium, or coma, with increased heat of the scalp, be present; the affusion of cold water on it, or cold applications, should not be neglected. If the disease be not only complicated, but also adynamic, a combination of the means advised in this and the preceding paragraph, according to the predominance of vascular determination, and of impaired vital power, will be necessary. — If *diarrhœa* or *dysenteric symptoms* exist, the internal and external means, already advised (§ 203.), especially the vapour bath, the warm epithems, the combination of diaphoretics with opium, &c. will be most appropriate.

205. *B. Treatment in the Intermisions.* — Having, by the above means, prescribed appropriately to the different forms and states of the disease, conducted the paroxysm to a safe conclusion, the next object is to *prevent its return*. — Our endeavours to fulfil this intention should be equally strenuous in all the forms of ague; for, although the fit has been slight, a much severer one may follow. Even a comparatively and apparently slight paroxysm may produce almost irremediable mischief in an important viscus; and however mild, its frequent return often occasions serious structural change.

206. *a.* After the paroxysm, and especially if the disease be recent, an *emetic* should be admi-

nistered, and its operation promoted by diluents. If it have been given at the beginning of the fit, and acted freely, it may be dispensed with now. But it should not be administered if symptoms of determination to the brain, or of inflammatory action of the stomach, liver, or spleen, be present. After its full operation, a large dose of *calomel* — from ten to twenty grains — ought to be given; and, about four or five hours afterwards, a *purgative draught*. If these act not sufficiently in a few hours, a cathartic enema should be exhibited. Having removed local congestions or general plethora by *depletions*, and evacuated morbid secretions and faecal accumulations, *cinchona* or the *sulphate of quinine* may be exhibited, to prevent the return of the fit. These are almost indispensable preliminaries to the quinine or bark, especially in the complicated and congestive forms: for, without them, it will either not be retained on the stomach; or, if retained, will convert congestions, or slight forms of inflammatory irritation, to active inflammation, or to structural change.

207. *b.* If the stomach remain irritable after the fit; or if pain or tenderness at the epigastrium, with other symptoms of inflammatory irritation or congestion, be present; the full dose of *calomel*, either alone or with opium, ought not to be withheld; for, as Mr. ANNESLEY has shown by his instructive experiments (*Sketches of the Diseases of India*, &c. 2d ed. p. 374.), this remedy has the effect, in large doses, of diminishing vascular action in the stomach and in the upper portions of the intestinal canal. When prescribed after depletions, general or local, and the external measures described above (§ 203.), the internal disorder will be removed, and the quinine, which is almost indispensable to the arrest of the disease, will be retained without uneasiness. If *quinine*, especially its sulphate, cannot be procured, the *bark* in substance, in large doses, must be substituted; and conjoined with ammonia, or camphor, capsicum, or opium, &c. shortly before the expected accession of the paroxysm. The decoction with serpentaria, the extract, or the compound tincture, may likewise be employed, but chiefly as an adjuvant. In every state of the disease, during the exhibition of quinine or bark, the excretions demand attention: a full dose of *calomel*, especially in warm countries, ought to be given from time to time, and followed by active purgatives and enemata. If the alvine excretions, and the biliary and other secretions, be not freely promoted during the exhibition of bark or quinine, great risk of superinducing inflammation, congestion, obstruction, and enlargement of the abdominal viscera, or violent determination to the head, will be incurred.

208. *c.* If the disease have been of long standing, congestion, obstruction, or enlargement, or chronic inflammatory action in some abdominal organ, has probably taken place. In these, the immediate use of *bark* or of quinine will be of doubtful efficacy. The treatment should, therefore, be commenced with sufficient local depletions, followed by the external means already noticed (§ 203.), and by the repeated exhibition of purgatives, a full dose of *calomel* having been pre-nised and given again at bed-time, as circumstances may require. This treatment is especially indicated in those more severe cases in which the intermissions are imperfect, the tongue much loaded, and fulness, distension, or uneasiness in

the upper regions of the abdomen, are complained of. Morbid secretions and local disorder being removed by these means, the sulphate of quinine or bark should be prescribed, at first either with purgatives, or alternately with those which will act decidedly. It is chiefly to a neglect of this practice that complications and unfavourable consequences so often follow the use of bark, quinine, or of arsenic; for these often interrupt excretion, and over-excite and inflame loaded, obstructed, or congested organs.

209. *d.* When the patient cannot be removed from the continued influence of malaria during the treatment, we must nevertheless trust to the energetic employment of the above means; thereby removing morbid secretions, improving the secreting and excreting functions, subduing local disease, and making a powerful tonic impression upon the organic nervous system and digestive organs. With this last view, the doses of quinine or bark should be as large as the stomach will bear, and exhibited shortly before the expected return of the paroxysm, or immediately after the sweating stage, when the intermissions are short or incomplete. Its effects will often be promoted, and it will not so readily offend the stomach, if it be given with camphor, opium, capsicum, pepper, cinnamon, &c. according to the peculiarities of the case. In these circumstances, as well as when the disease presents an adynamic form, or is more or less complicated, especially when the tongue is much loaded, or flabby and pale, the paroxysms prolonged, and the intermissions imperfect, *calomel* in full doses, at bed-time, either alone, or with James's powder or opium; a warm stomachic purgative the following morning (F. 216. 266.), thereby procuring three or four evacuations daily; and the quinine alone, or combined in the manner just stated, during the intermissions, or until the accession of the cold stage; are most to be depended upon. If the spleen be much enlarged, and the patient subjected to the enervating influence of malaria, *calomel* must be given with greater caution, and its effects watched. In such circumstances, the purgatives selected should be prescribed with a tonic; as the sulphate of quinine with the sulphate of magnesia; the decoction of bark with the sulphate of magnesia and the tincture of senna, or with the compound decoction of aloes; or the compound infusion of gentian, or the infusion or decoction of cinchona with the infusion of senna, and warm tinctures.

210. *e.* In cases of protracted, irregular, complicated and reduplicating ague, as well as in those of a low form, and in those occasionally following remittents or continued fever in warm climates, the *liver*, *spleen*, and *digestive mucous surface*, are generally more or less diseased. The intermissions, even when distinct or perfect, are accompanied with great languor, general uneasiness, want of appetite, a foul or loaded tongue, a sense of oppression in the epigastrium and hypochondria, and unhealthy countenance and skin; the upper abdominal regions being often full, tumefied, or tense. Here, local depletions, if they be not contra-indicated, and *calomel*, followed by purgatives, as already advised, should precede the exhibition of quinine. We must not, however, wait for the removal of these signs of congestion and obstruction, before resorting to quinine or the bark; for the patient may sink too low, and vital

power become insufficient to resist the progress of disorganisation. It should, therefore, be given as soon as free evacuations have been procured, and the tongue begins to clean. As long as the tongue is moist, the circumstance of its being loaded must not prevent the administration of quinine, if it be otherwise indicated; but it should be conjoined with a purgative, or the latter ought to be given in the intervals between its exhibition. In ordinary circumstances, I have prescribed calomel, or blue pill, with or without opium, at bed-time; an active and stomachic cathartic early in the morning; and quinine or the bark in a large dose, with camphor, &c. shortly before the return of the fit, or soon after the subsidence of it, when the intermissions are short.

211. *f.* When the liver becomes enlarged, and more especially if it be also tender or painful on examination, local depletions followed by fomentations and poultices; in some instances by the turpentine epithem; in others by blisters, and a judicious employment of purgatives, and of the bark or quinine; as circumstances may warrant, are indispensable. In most instances of enlargement of the liver consequent upon ague, purgatives, if appropriately combined, and firmly persisted in, have a most remarkable and beneficial effect. If enlargement be connected with torpid function, or if the latter only be present, the mercurial ointment with camphor may be rubbed over the hypochondrium; or a large plaster formed of the *emplastrum ammoniaci cum hydrargyro*, or of it and the *emplastrum picis*, or the warm *nitrohydrochloric lotion*, may be applied over the hypochondrium and epigastrium. An issue or seton in the right side may also be resorted to if the above fail. In cases of enlargement of the spleen, in addition to the use of tonics and purgatives conjoined, the turpentine epithem, or the plaster, or the lotion just mentioned, may also be tried. In all cases of ague, and especially in the protracted, the adynamic, and the complicated, the excretions, particularly those from the bowels, should be carefully and daily examined; and from these, from the appearance of the tongue, the hue of the skin and countenance, and from the state of the abdominal regions, should our therapeutical inferences chiefly be drawn. The presence, however, of enlargement of the liver and spleen, especially of the latter, although requiring other and appropriate remedies, must not prevent us from having recourse to quinine; for the ague must be removed as soon as possible, in order that its repeated return may not increase the local affection; and as soon as this object is attained, the local disorder will the more readily yield to proper means.

212. *C. Remedies employed to prevent the return of the fit.* — The most certain of these, quinine and bark, have been already noticed. But numerous other substances have a similar operation, although in a much slighter degree. Indeed, any substance which stimulates, in a more or less permanent manner, the nervous system of organic life, tends to efface or to supersede the morbid state or impression made upon this system by the exciting cause of the disease. Hence stimulants and antispasmodics have a febrifuge action, although in a much less degree than bark; and even affections of the mind of an exciting kind exert a similar influence; whilst the depressing passions increase the malady, tend to complicate

it, and cause an earlier as well as a severe return of the paroxysm.

213. *a. Cinchona, or Peruvian bark*, was brought to Spain in 1632, and came into use in England in or about 1655. It soon afterwards fell into discredit, so that CROMWELL died of ague without the exhibition of it. According to Sir G. BAKER, Drs. PREJEAN, BRADY, and WILLIS, countenanced its employment; but STURMIUS (*Febrifugi Peruviani Vindiciorum, Pars prior*. Antw. 1659.) first established its reputation. SYDENHAM, MORTON, and LISTER extended it in this country, and ascertained the circumstances in which it was most beneficial. The preparation of quinine and cinchonine from the bark, and the combination of the former with sulphuric acid — the sulphate of quinine — has been one of the greatest triumphs of pharmaceutical chemistry. This latter substance has, since 1820, in most instances of ague, superseded the bark, as the small dose in which it is exhibited — from two to ten grains — renders it less offensive to the palate and stomach. After morbid matters have been evacuated from the bowels, it may be given in a full dose — six or eight grains — immediately after the fit, or shortly before its return; or a large dose followed by smaller doses every three or four hours; or the latter by the former, may be exhibited. Inflammatory or congestive complications do not contraindicate its use, as shown above, if the requisite evacuations have been practised; for, in ague especially, the almost simultaneous employment of depletions, purgatives, and quinine, is often both appropriate and beneficial. The quinine or bark should be continued, and the digestive functions carefully attended to, for a considerable time after the disappearance of the fits. In cases where even the sulphate of quinine cannot be taken in sufficient quantity without offending the stomach, M. DE MARTIN (*Rev. Médicale*, Sept. 1827.) has shown that it may be applied efficaciously to the skin denuded of the cuticle, having reduced it to very fine powder and mixed it in cerate. It thus is absorbed into the circulation, and acts upon the organic nervous system through the medium of the vascular system, with which the former is so intimately associated.

214. *b.* Dr. FOWLER's solution of arsenic holds the next place to quinine or bark in the cure of ague. Dr. BROWN advises it in preference to quinine, when ague is attended by inflammatory determinations. This may be the case, but I have found quinine, employed as above directed, or given in solution with a neutral sulphate, as that of soda or magnesia, equally beneficial in such cases with the arsenical solution. The dose of this solution should not exceed twelve drops, given every four hours during the intermission, either alone, or with a few drops of laudanum, or with the tincture of hyoscyamus. The sulphate of zinc, in doses of two or three grains every four hours, or as much as the stomach will bear, is also efficacious; but chiefly in mild cases, or when inflammatory action is present. It was much praised by Sir G. BLANE, and is the best emetic that can be prescribed in the disease. The hydrochlorate of ammonia is also capable of arresting the fits, and is best given in an infusion of cinchona, or of orange peel, or of cloves, in as large doses as the stomach will retain. It was much employed by MUYS, WERLHOF, SENAC,

PRINGLE, and BROCKLESBY; and is most appropriate to the inflammatory states of ague. MOR-
TON gave a scruple of *chamomile flowers*, ten grains
of salt of wormwood, and as much of the calx of
antimony, every sixth hour; Dr. HEBERDEN,
myrrh in large doses; and Dr. CULLEN, *tormentil*
and *gentian* with *galls*.

215. c. The preparations of iron have been
employed, especially the *ferri ammonio-chloridum*
by STAHL, TRILLER, HUXHAM, and HARTMANN.
The *cyanide of iron* has lately been strongly re-
commended by ZOLLICKOFFER, who prescribed it
in doses of four grains twice or thrice daily.—The
trinitrate of *bismuth* has likewise been given by
HENKESEN; *phosphorus* with bark, by HUFELAND;
the flower of *sulphur*, in full or large doses, by
RIVERIUS and DE HAEN; powdered *carbon*,
in doses of two drachms, shortly before the fit, by
PIERQUIN; *ammoniated copper*, by M'CAUSLAND,
BIANCHI, and BRERA; *DIPPEL'S animal oil*, by
WERLHOF and HALLER; and *cobweb*, by PAULINI,
GRANT, and JACKSON.—I have given the *chlorate*
of potash with benefit in the decoction of bark, and
in the infusion of valerian, with a little tincture of
capsicum. *Charcoal* was employed in ague by
JACKSON, CALVERT, and TULLY (*Edin. Med. and*
Surg. Journ. vol. x. p. 15. 403.), and was found of
service when the gastro-intestinal mucous surface
was much affected.

216. d. The barks of various astringent, tonic,
and aromatic trees and plants have been tried,
both before the introduction of the *cinchona* into
practice, and subsequently as a substitute for it.
The most esteemed of these are the *willow bark*.
This substance was prescribed by CLOSIUS, GÜNZ,
STONE, RESENBLAD, THILENIUS, HILSCHER,
JAMES, STYX, and WHITE; the *angustura bark*,
by WILKINSON and BRANDE; the bark of the *Swie-*
tentia febrifuga, by ROXBURGH; *cascarilla bark*,
by HECKER and others; the *pomegranate bark*,
by REHMANN; the bark of the *Ilex aquifolium*, by
ROUSSEAU; the barks of the *chestnut tree*, of the
elm, and of the *oak*, by various writers; and the
carapa bark of South America, which has been
said to have succeeded where *cinchona* had failed.
Various other stimulating, aromatic, and tonic
vegetables have been employed, and some of them
are still in use, either as adjuvants of the bark, or
of quinine; or in the form of infusion, as vehicles
for other substances. The most useful of these are
quassia; *serpentaria* (LYSONS, &c.); *Calamus*
aromaticus (GULBRAND, MOSELEY, and HORN); *arni-*
ca (ASKOW, &c.); and *Capsicum annuum*
(BERGIUS and myself).—*Ammonia*, *camphor*, the
athers, *castor*, *musk*, *myrrh*, *ginger*, *black pepper*,
garlic, *mustard seed*, &c. have likewise been em-
ployed, chiefly as adjuncts to more permanent
stimulants and tonics, or in large doses with opium,
shortly before the accession of the fit. Of these,
the most serviceable are *camphor* and *ammonia*.
Piperin, the active principle of black pepper, has
been lately employed by BERTINI, GORDINI, and
others, in doses of one or two grains, to arrest the
paroxysms; and *salicina*, and alkaloid found in
willow bark, has been very recently recommended
as a substitute for quinine. *Ignatius's bean*, and
the preparations of *nux vomica* were formerly used
against ague, by PAULINI, BOURIEU, ASKOW,
CULLEN, HORN, and FOUQUIER; and their ac-
tive principle, *strychnia*, may also be found useful
in the lower grades of the disease, especially when
complicated with *diarrhœa*; in which, as well

as in the *dysenteric* complication, the tormentil,
ipeacacuanha, Dover's powder, the hydrargyrum
cum creta, and opium, are useful adjuncts to
other medicines.

217. e. The mineral acids, especially the *hy-*
dro and *nitrochloric*, have been given in the
decoction of bark, especially when the liver or
spleen have been enlarged. I have employed
the latter in such cases; and, in a state of very
weak solution, as a common beverage for the
patient during the intermissions. The *sulphuric*
acid, similarly exhibited, has been recommended
by STORCK and JOERDENS. It is an useful ad-
junct to the sulphate of quinine. The *citric* and
acetic acids have been directed, but chiefly as an
addition to the drink taken in the hot stage, in
which, however, acid drinks should not be taken,
as they tend to diminish the perspiration, which is
more or less salutary.—*Ethers*, especially the
sulphuric and *hydro-chloric* have also been pre-
scribed in large doses, either alone, or with *cam-*
phor and opium, shortly before the paroxysm, with
the view of shortening the cold stage (HOFFMANN,
CLUTTON, and DAVIDSON).—The *volatile alkali*
has been likewise employed similarly combined,
and with the same intention; and the various pre-
parations of *antimony* have been given before and
during the paroxysm, and throughout the inter-
missions, in conjunction with bark or other febrifuge
tonics. *Alum* was at one time much used in
ague, it having been recommended by ETTMÜLLER,
LINDT, MÜELLER, and others. LANGE and DE
MEZA prescribed it with aromatics, and sulphuric
acid, or ather; and ADAIR, with *cinchona*.—
The *sulphate of iron* has been tried by several
writers; but is of inferior efficacy to the sulphate
of zinc, or to the *tincture of the sesqui-chloride of*
iron. The *Prinos verticillatus*, and the bark of the
Prunus Virginiana, and *P. silvestris*, have been
mentioned in favourable terms by BARTON and
other writers; the bark of the *pine*, by BERZELIUS;
and *valerian* and *gentian*, by VAIDY and
others.

218. f. *Anodynes* have been used in conjunction
with, and as adjuvants of, antispasmodics, stimu-
lants, and diaphoretics. *Opium* has been exhi-
bited with these, and with antimonials, shortly
before the fit, by M'CAUSLAND, BREGDA, and THOM-
MANN; with *camphor*, by SENAC and AMELUNG;
with *ipeacacuanha* and nitre, by DOVER; and with
aloes and camphor, by AUDOUARD. The extract of
belladonna has been prescribed with bark and
other tonics, by HUFELAND and ERDMANN; the
Laure-cerasus, by BROWN LANGRISH; *bitter al-*
monds, by BERGIUS; and the powdered leaves of
the *Laurus nobilis*, by Sir G. BAKER, given in
doses of two scruples, in bitter decoctions, shortly
before the paroxysm.

219. g. In old and protracted cases, attended
by infarction of the abdominal viscera, *mercurials*,
especially calomel, have been employed in fre-
quent doses, until slight salivation was produced,
by WILLIS, STAHL, BAKER, and LYSONS; and the
propriety of the practice, in some circumstances,
is confirmed by more modern experience.—In
similar cases, repeated *frictions* of the surface have
proved serviceable, especially with some one of
the liniments prescribed in the APPENDIX (F. 299.
311.). Frictions along the spine, with stimulating
substances, have been advised by HAUTESIERK,
VAN SWIETEN, DE HAEN, TRNKA, and others; *rubefacients* and *blisters* over the epigastrium and

upper regions of the abdomen have been directed by KORTUM, SCHLEGEL, and the writers just quoted; and are of essential benefit in congestions, inflammatory irritations, or obstructions of the abdominal viscera, and in the low forms of the disease. Frictions with the *antimonial ointment* have been preferred by M. PEYSSON. Compression of the lower extremities by ligatures, shortly before the paroxysm, has been advised by TROTTER and KELLIE; and the *cold bath* during the intermissions has received, since the appearance of the work of Dr. CURRIE, numerous and often indiscriminating trials. In the simple form of ague, or during convalescence, when the practitioner is convinced, by a careful examination of the patient and the state of the excretions, that no complication exists, either a common plunge bath, particularly in sea-water, or the *shower bath*, will often prove serviceable, especially when it is followed by a genial glow on the surface.

220. *h. Masked or anomalous ague* requires a nearly similar treatment to that already recommended. The decided and repeated use of cholagogue purgatives, both before, and alternately with, a liberal use of quinine, or other tonics, or of the *sesquioxide of iron*, especially when the complaint assumes a neuralgic character; change of air, and attention to the digestive and excreting functions, are the chief and most successful remedies. In the more painful or spasmodic forms of these affections much advantage will accrue from conjoining quinine with camphor and colchicum; neither these nor other stimulants or antispasmodics impairing the sedative action of colchicum, in as far as regards pain. In some cases of this kind I have given the chlorate of potash in the decoction of bark, and the infusion of valerian with camphor and the compound tincture of colchicum, with benefit. The *alkaline carbonates* in large doses, with energetic tonics, and the *kreosote*, are also sometimes efficacious.

221. *D. Treatment of the Sequela.*—The treatment of agues should not terminate with the discontinuance of the paroxysms. The functions of the digestive and excreting organs must be restored, and the more severe consequences of the disease in the abdominal viscera removed; otherwise, a return of the fits will follow the slightest causes; or the obstructions in these viscera will induce very serious structural lesions. Certain of the complications are also among the most serious sequelæ of ague, especially diseases of the liver, mesenteric glands, large bowels, &c.; for these may both accompany and remain after the fever; or they may not be very manifest, although doubtless previously existing, until the fever has disappeared. This is not infrequently the case with dysentery and chronic diarrhoea, particularly in warm climates; and with dropsies in this country, which, however, are only contingent consequences of the disease. The treatment must mainly depend upon the nature of the consecutive affection, which, as respects the liver, commonly consists of enlargement, chronic inflammation, or both, with or without more or less obstruction of the portal circulation, or of the biliary secretion. In either case the means which have been recommended by Mr. ANNESLEY and myself, viz. local depletions, followed by repeated blisters or setons; a full dose of calomel, taken occasionally at bedtime; the hydrargyrum

cum creta or blue-pill the intervening nights; and mild purgatives early in the morning; will be found most beneficial. After these have been persisted in, according to the nature of the case, and the more active symptoms have been entirely removed, this organ continuing torpid, the *nitro-hydrochloric acids* used both internally and externally, and exercise on horseback, will be of service; but mercurials must have been relinquished some time before the use of the acids. Lastly, a course of Cheltenham or Harrogate waters, or judicious substitutes for them, used daily and perseveringly, will confirm the recovery.

222. If the *spleen* or the *mesenteric glands* be enlarged, frictions of the abdomen with warm stimulating liniments (F. 311.)² stomachic purgatives, as aloes, rhubarb with sulphate of potash, and small doses of the sulphate of iron; the iodide of potassium in moderate doses; and blisters, setons, moxas, &c. will be found most successful. In neither of these states of disease will depletions be required, unless pain and tenderness on pressure be complained of, when local depletions, followed by blisters or the turpentine epithem, will be sufficient.—The most appropriate treatment, in cases of consecutive *dysentery* and *dropsy*, is fully described in these articles.

223. *E. The diet* during the intermissions should be light, nourishing, in very moderate quantity, and taken at a time not too close upon the accession of the paroxysm. If the disease be of an inflammatory form, or associated with active determination to an important viscus, *abstinence*, as directed by CELSUS, SENAC, TESSIER, &c. should be observed. Whilst purgatives are being employed, broths and weak soups are most suitable. In the paroxysm, diluents only are admissible.

224. *F. During convalescence*, strict attention should be paid to the diet and regimen, and to the states of the digestive and excreting organs. The latter should be assisted occasionally, and always when they are sluggish, by the usual means; and quinine, the other preparations of bark, or different tonics, should be continued for some time after the disappearance of the paroxysms. Regular and moderate exercise, especially on horseback, also, will materially promote recovery. Exposure to cold easterly or northerly winds, or to the night air and moisture, ought to be carefully avoided; and if change of air cannot be enjoyed, or if the patient be still liable to be exposed to malaria, the *Prophylactic Measures* advised in the article ENDEMIC INFLUENCES (§ 20.) should be adopted as far as circumstances will permit.

XII. REMITTENT FEVER. SYN. — Exacerbating, Paroxysmal, Sub-continual, Endemic, Endemial, and Endemical, Fever, of various writers.

225. DEFIN. — *The febrile phenomena evincing striking exacerbations and remissions, one paroxysm occurring in the twenty-four hours.*

226. This fever, although holding a middle rank between agues and continued fevers, approaches the former most nearly in its causes, phenomena, and consequences. It is most common in warm climates, and in the warmer countries without the tropics, in which it is most prevalent in summer and autumn. It is strictly a disease of locality and climate, and hence very generally denominated *endemic*; but as climates and localities vary remarkably, so is it modified in character from the mildest form, in which it is similar to simple ague in every respect but the complete remissions, to the more malignant states, in which it so nearly approaches yellow fever in warm countries and seasons, and continued fever in temperate climates, as to have been frequently confounded with them. To intertropical practitioners, especially, as well as to those in temperate countries which abound with the endemic causes of disease, this fever presents great interest. It is not infrequent in the vicinity of London; and in marshy localities in the southern counties of England, and Ireland, during the summer and autumnal months.

227. i. CAUSES. — *The predisposing and exciting causes* have been noticed above (§ 194.), and more especially in the articles *DISEASE* (§ 31. 55.) and *ENDEMIC INFLUENCES*. *DR. CHAMBERS* has supposed that remittents arise from two principal sources: — 1st, from marsh-miasmata; 2dly, from sudden vicissitudes of atmospheric temperature precipitating some other deleterious principle evolved from hidden sources. — Of this latter, however, we can have little or no knowledge; and, even granting the evolution of such a principle, we have no evidence of any sources from which it can arise different from those pointed out in the articles now referred to. As, therefore, the exciting causes of endemic fevers in adults are chiefly emanations from the soil — from decaying organic bodies on its surface or commingled with it — and from stagnant putrid water; and, as these causes are necessarily varied in concentration, activity, and in their nature, according to the states of the air, and to the varying proportions of vegetable and animal matters undergoing decay, so it must be inferred that the effects produced by them, even when the constitution of the recipients is the same, will be also varied: but, when we consider the great variety of habit, organisation, temperament, and susceptibility, it must necessarily be concluded that the forms and states of fevers resulting from

these causes must be still more remarkably diversified, and will vary, not merely in type, from a simple tertian, through the remittent forms, to a purely continued state; but also as to vascular action, vital manifestation, and visceral complication. Remittents, therefore, and as observation has repeatedly proved, are merely severer grades of the same pathological states as constitute intermittents; a more concentrated form, or intense action of the exciting causes which produce the latter, either absolutely or relatively to the predisposition or susceptibility of the individual, also occasioning the former. That concentration of the exciting causes, or intensity of action, is, in some measure, concerned in creating the difference, is shown in the constant residents of an unhealthy locality having ague at one season, when the exhalations are rationally inferred to be neither abundant nor intense; and remittents at another, when these causes are either the one or the other. That the state of the recipient has a marked influence, is proved by persons recently arrived in districts productive of endemic fevers having some one of the forms of remittent at the same time and place as those who have been long resident have ague. Remittents are most prevalent in autumn, next so in summer, and the least so in spring. They rarely occur in winter, in temperate countries, unless in those which nearly approach the tropics.

228. ii. DESCRIPTION, &c. — From the varying forms remittents assume, owing to the circumstances just mentioned, it is evident that all *divisions* of them must be purely conventional, and founded on degrees of severity, and on alterations of their most prominent features. M. BEAUMES has distinguished them into three grades — the *severe*, the *less severe*, and the *benign*; and M. BOISSEAU into the *inflammatory*, the *bilious*, the *mucous*, the *adynamic*, and the *ataxic*. The last three of these are merely modifications of the adynamic, as respects the state of vital power and vascular action. I shall adopt a nearly similar arrangement to that which I have stated above (§ 44.).

229. A. *Mild remittent* appears after slight ailments of several days duration; the precursory symptoms being chiefly uneasiness at the epigastrium, lassitude, and pains in the back, limbs, and head, with restlessness at night. These may continue for some time; the *formative period*, or the time elapsing from the impression of the cause to the *invasion* or development of the febrile phenomena varying from five or six to about thirty days, as determining or accessory circumstances may arise to accelerate or reinforce the action of the chief cause. The stage of *invasion* is similar to that already described; it being attended by coldness of the surface, and frequently by shivering. The coldness is soon superseded by heat, by febrile flushes, or by alternations of heat and cold, by nausea, and occasionally by vomiting, which soon develope the stage of *excitement*. With it, the pains of the head, back, and limbs become remarkably aggravated; the mouth is clammy and dry; the tongue white or loaded; the surface very hot and parched; the face flushed; the features tumid; and the pain of the head attended by a feeling of distension and throbbing, often passing into delirium. The pulse, which, at the invasion, was small, irregular, and weak, is now full, large, strong, and

frequent; thirst is urgent; the bowels constipated; and the urine scanty and high-coloured. There is always more or less tenderness at the epigastrium, with nausea, and often with vomiting. These symptoms generally continue from about ten or twelve to eighteen hours, when perspiration breaks out; the pulse falls in frequency and strength; the irritability of the stomach subsides; delirium disappears; and the skin becomes cooler: but there is merely a remission or abatement, but no intermission, of the febrile symptoms. The remission usually continues from three to nine or ten hours, when an exacerbation occurs, sometimes preceded by chills or shiverings, at other times not, and the severer symptoms are renewed. Thus the disease proceeds with alternate remissions and exacerbations, the former generally taking place in the morning, until the seventh day, or the ninth, eleventh, or fourteenth day, or much later, in temperate countries, when a copious perspiration generally puts a termination to its progress. This form of fever has a particular disposition, as Dr. JACKSON has remarked, to a favourable critical change on the seventh, fourteenth, twenty-first, and twenty-eighth days; but in warm countries it seldom continues longer than fourteen days.

230. B. The *inflammatory form* frequently attacks sanguine plethoric Europeans residing in warm miasmatic climates. It differs from the foregoing chiefly in grade, and the greater degree of vascular reaction in the period of excitement, which is sometimes so great as to exhaust the tone of the vessels and the powers of life, and even to change the blood, thereby simulating some forms of epidemic or continued fevers, especially when the remissions become obscure, as is often observed in the worst cases. It commences either as the foregoing, or with rigours, pain and sickness at stomach, and oppression at the præcordia, followed by vomiting, headach, great dejection of spirits, and mental delusions of a low or gloomy kind, sometimes impelling the patient to suicide, which, in two instances, I have seen attempted even before much complaint had been made. In other cases, the patient falls down in a state of syncope, following several days of indisposition, with a cold pale surface, and dejected countenance. The pain of the stomach and head increase, is attended with vomiting, sometimes of bilious matters, at other times of a whitish fluid, with fulness and tenderness at the epigastrium. The vomiting is generally followed by vascular reaction: the pulse, from being small, weak, irregular, or intermitting, becomes full, strong, and very quick; the face injected and tumid; the eyes prominent, watery, and red; the thirst intense; the throat arid and sore; the tongue furred, its edges red; and the headach and delirium increased. In about twelve or fourteen hours a copious perspiration breaks out, the symptoms subside, and the pulse falls to about ninety. After a short remission, the thirst, pain at the stomach, headach, &c. are aggravated, and the delirium and vomiting return. If the disease be neglected at the beginning, the remissions disappear, the skin becomes dry and caustic, or moist and clammy; the pulse small and irregular; the tongue black and crusted, and the vomiting, pain at the epigastrium, &c. more

constant. In the most severe and unfavourable cases, yellowness of the skin, or vomiting of matters like coffee-grounds, or both, occasionally supervene. The bowels, which, before the attack and at its commencement, were torpid, are, at further advanced stages, irritable; the evacuations being watery, greenish, and, at last, almost black; the urine being very scanty and high coloured. If the disease be not actively treated at the commencement, an unfavourable termination takes place between the third and seventh days; but it is often prolonged beyond this period, and it then generally occasions visceral disease.

231. Such is the inflammatory remittent of warm climates. A nearly similar fever attacks unseasoned Europeans lately arrived in the West Indies and inter-tropical Africa, and often presents an obscurely remittent or almost continued type. It has been very generally mistaken for true yellow fever, owing to the malignant symptoms it assumes at an advanced period, or state of exhaustion consequent upon the vascular excitement of the early stage. The inflammatory remittent, the bilious inflammatory, the adynamic or malignant remittent, and the ardent or seasonal fevers of Europeans lately arrived in warm countries, are merely modifications of each other, and differ essentially from epidemic yellow fever, with which, however, they have been all most singularly confounded.

232. *C. Bilio-inflammatory remittent fever* differs but little from the foregoing in its characters and course. It is most prevalent in Europeans who have not resided long in a warm miasmatic country, and in low marshy localities, or in thickly wooded districts. In temperate climates, it is observed chiefly in the autumns consequent upon very warm summers; and in the bilious or bilio-sanguineous constitutions. It is often dependent upon the vicissitudes of season, especially wet seasons following great warmth, or a very hot summer consequent upon a wet spring; and it is often very prevalent or almost epidemic during the hot months, after very heavy rains, within the tropics. Violent determination to the brain characterises the commencement of reaction, in this variety; and inordinate affection of the liver and digestive mucous surface, the more advanced stages. Pain in the head is most severe, especially in the forehead and sockets of the eyes; the conjunctiva is yellow or suffused; the countenance and skin become dusky or yellow; the tongue is loaded by a bilious coating; and the evacuations are bilious; especially the matters thrown off the stomach. The bowels are at first costive, but they afterwards often become irritable or dysenterically affected. After the vomiting has continued some time, the appearance of the matters is changed, and ultimately assumes in fatal cases the characters just described (§ 229.).

233. *D. The adynamic or malignant remittent* is one of the severest and most fatal of endemic fevers. — *a.* It is observed only in places where the endemic causes are concentrated or intense relatively to the state of predisposition; and is seldom ushered in by shiverings, but generally by a prolonged sense of cold, universal collapse of the vital powers, and of vascular action. Pain in the head of a peculiar constrictive kind; mental depression and insane delusions; imperfect efforts

at reaction; remarkable lassitude and pain in the loins and limbs, are present at the commencement, with great anxiety, pain, and oppression of the præcordia, and nausea, sometimes giving rise to vomiting, which assists in developing the stage of excitement, and in partly overcoming the inter-nal congestions. The pulse is small, constricted, or irregular; the skin becomes dry and caustic, or moist and clammy; and impresses the hand of the observer with an acrid or tingling sensation; the eyes are watery and injected; the tongue is clammy, moist, or flabby and coated, and afterwards dry, rough or brown; the face is flushed, but dusky or purplish: the bowels are costive, subsequently relaxed or irritable, and the urine is scanty, high coloured, or suppressed. After twelve or fourteen hours, a slight remission is observed, after which the symptoms are exacerbated; the stomach is remarkably irritable; the epigastrium painful and tumid; the breathing hurried; and the patient restless and distressed. In the more dangerous cases, hiccup, constant vomitings, yellowish discolourations of the skin, exudations of blood from the digestive mucous surfaces, low delirium, and death, supervene between the fourth and seventh days.

234. *b.* This variety is variously modified, in different circumstances and persons. It sometimes assumes more of a cerebral or typhoid character; at others, it is bilious or gastric, according to peculiarity of season or concentration of the cause. In some inter-tropical countries it becomes epidemic, or rather this endemic is more than usually prevalent. Occasionally the remissions are indistinct from the commencement, and they generally become so after three or four days. — *α.* In some cases the vascular excitement is at first more or less intense, with remarkable determination to the head, liver, and stomach, and maniacal delirium, the disease very nearly approaching the inflammatory, or bilio-inflammatory forms. — *β.* In others, vascular reaction is very low and imperfect; the pulse small and quick; the abdomen tumid and hot, whilst the extremities are cold or clammy; the evacuations foul, morbid, and offensive; the tongue fuliginous; the gums, spongy, or oozing a bloody sanies; the vomiting constant, and ultimately grumous and dark; the stools towards the close, black or pitchy; the urine scanty or nearly suppressed; the solids flaccid; and the skin earthy or discoloured. In both these states, a yellowness of the surface occasionally presents itself about the third or fourth day, beginning in the conjunctiva, neck, and breast. The yellowness often passes to a pale greenish hue, in patches, shortly before death; and the soft solids present a liquescent state, having lost their vital cohesion.

235. *c.* In other cases of this form, the symptoms are at first mild, and the excitement inconsiderable; when, after two, three, or four exacerbations, the powers of life appear suddenly exhausted; the pulse becomes weak and fluttering; the tongue foul, black, and dry; the evacuations offensive; the prostration of strength extreme; and the factor of the perspiration remarkable. At last, great anxiety; tenderness and tension of the epigastrium; fulness of the hypochondria; collapsed features; a squalid or yellowish surface; vomiting of dark or grumous matters, supervene, and indicate the utmost

danger. This insidious modification of the adynamic form generally occurs in persons highly predisposed, or who have suffered from bowel complaints, or who are debilitated, and are subjected to the more concentrated effluvia.

236. *d.* In some instances the remittent commences in so mild a form, that the patient is even able to walk about his apartment; and, for several days, complains only of irregular exacerbations of fever, when, suddenly, violent and malignant febrile action supervenes, which rapidly exhausts vital power, and either quickly carries off the patient, or induces serious structural change in several of the abdominal organs. In other cases, vascular excitement is hardly manifest at any period of the disease; the exacerbations consisting merely of increased anxiety, restlessness, general distress, and mental depression, occasionally with augmented sickness; and pain in the head, epigastrium, and loins; the pulse being but little accelerated until the close, and the temperature, unless at the epigastrium, rather under than above natural. In these, however, the weak, soft, and open or irregular pulse; the dark-coated, or soft, flabby, and lobulated tongue; and the blackish-greenish-brown, and morbid excretions, in connection with the other symptoms, denote extreme danger. It would seem as if the causes had nearly annihilated the irritability of the moving fibres, and deprived the system of its ability of reacting upon, or superseding, the morbid condition induced by their first impression.

237. *E. Complicated Remittents.*—Complications are observed in the inflammatory, bilio-inflammatory, and adynamic forms; the alterations that take place in the seats of predominant disease, being the chief causes of unfavourable terminations. The importance, therefore, of recognising them at an early period must be evident.—*a.* Amongst the earliest complications in remittents are *inflammatory states of the mucous surface of the stomach and duodenum*. This condition is indicated by constant irritability of stomach; by fullness, heat, and tenderness of the epigastrium; and by a foul loaded tongue, with red sides and apex. This pathological state often extends to the *small intestines*, and even to the *large bowels*, as indicated by tumefaction and tenderness of the abdomen; by a sense of inward soreness or heat; by irregularity of the bowels, or frequent, scanty, and morbid evacuations; and by diarrhœa or dysenteric symptoms. If the *large bowels* be chiefly affected, the dysenteric symptoms are more urgent; and on examination soreness or tenderness will often be complained of in the region of the cæcum and course of the colon. Remittents thus associated often pass into, or terminate with, dysentery. The *gastric complication* is frequently induced by the irruption of an acrid bile at the commencement of the fever; the morbid state of this secretion irritating and inflaming the parts over which it passes. The *intestinal affection* probably arises from the same cause, or from accumulations of mucous sordes or other morbid matters in the bowels. But collections of acrid and morbid secretions and of faecal matters most frequently occasion the *dysenteric disorder*; and a morbid state of the bile frequently contributes its aid also in producing this complication.

238. *b. Disease of the liver* is a common complication of remittents, especially in the East

Indies and in warm climates; and even in this country. In most cases of this fever, the functions of the liver are disordered; but actual structural change is also common; and may appear early in the disease, or at later periods. The biliary secretion is most frequently increased; in a few cases it is diminished; and in some it is accumulated in the ducts and gall-bladder for a time, and is afterwards let loose, increasing the disorder of the stomach and bowels. But, whether in excess or diminished, it always is more or less changed in quality. The structural affections of the liver attending remittents are nearly the same that are met with in agues, excepting that inflammatory action, acute congestion, or moderate determination, affects its internal structure more frequently in the former than the latter, and the vascular action partakes more of the asthenic character. With congestion and inflammation, more or less enlargement also exists; and occasionally puriform matter is formed; but the latter is seldom evinced by diagnostic symptoms; signs of diseased structure of the viscus being only apparent. Even when horripilations or rigours do occur, they are liable to be mistaken for the cold stage of the paroxysm.—*Softening of the internal structure of the liver*, with or without congestion or enlargement, is a common lesion in the adynamic states of this fever. I have observed it most frequently after fullness, tenderness, a sense of burning, or pain in the right hypochondrium and epigastrium, with great anxiety, intense thirst; dark-coloured and loaded tongue, very quick and weak pulse; offensive evacuations, and dark grumous vomiting.—*Disease of the spleen* is a common complication in old European residents in hot climates, and in many localities in the south of Europe. It is similar in kind to that already noticed. In the low forms of remittent complicated with disease of the liver or spleen, the greatest care should be observed to avoid roughness in the examination of the abdomen and hypochondria. Too great or sudden pressure has produced irreparable injury in such cases.

239. *c. Determination to the brain* of an active kind, rather than pure inflammation, often occurs early in the more severe remittents. In the most prominent of this class of cases, the symptoms of cerebral excitement, and increased vascular action in the brain, are superseded by stupor, coma, low delirium, and typhoid or adynamic symptoms. The peculiar delirium, insane delusions, and mental depression or apprehension, which often affects the patient from the commencement, seems to be less the result of inflammatory action in the brain, than of impaired nervous and cerebral power. It often passes off, or it changes into a state of apathy or indifference to the result of the disease, and strong disinclination to take the medicines prescribed. This effect upon the spirits and mental powers evidently arises from the peculiar or specific action of marsh poison, which, as I know well from experience, occasions a distressing feeling of depression and despondency, even when it does not induce open disease. Maniacal excitement or delirium often passes into coma or stupor, and the patient expires as if in a quiet sleep.

240. *d.* The association of remittents with *pulmonary affections* is observed in temperate countries, especially in the spring and summer; and

more rarely in warm climates. The pulmonary functions are more or less impaired during the formative and invading periods; but acute disorder is seldom developed until the period of excitement, and consists chiefly of *bronchitis, catarrh, and pneumonia*, of a nervous or congestive form. In some cases *congestion* of the lungs, and of the bronchial surface, commences during or shortly before the period of invasion; and either partially continues throughout the disease, or passes into a low form of inflammatory action, and even into hepatisation. *Rheumatism* is also occasionally complicated with remittents; and *erysipelas* sometimes supervenes when a part is injured, the cuticle abraded, or the skin divided. *Ulcers* and *sores* not unfrequently take place on the lower extremities in the course of remittents, as well as of intermittents, particularly in low, wooded, and swampy districts within the tropics.

241. *F. The terminations of remittents* are — 1st, In restoration of the healthy functions; — 2d, In a chronic form of remittent; — 3d, In organic change of one or several important viscera, particularly of those which manifest predominant disease during the progress of the fever; — 4th, In fever of a different type; — 5th, In dysentery; — and, 6th, In death. Although any of the *consequences* pointed out above (§ 47. 189.) may arise, changes of the viscera of the abdominal cavity are by much the most common, in this class of fevers, as well as in agues. The *Prognosis* is apparent from what has been advanced, and in every respect agrees with what has been stated on the subject above (§ 57. *et seq.*).

242. *G. The lesions observed after death* from remittents, as respects both their seat and nature, differ but little from those already described in connection with agues. They, however, are of that kind which are generally observed to result from acute action in connection with deficient power. The *liver* is usually injected, remarkably softened, of a dark colour, friable, and sometimes enlarged. The *spleen* is often so soft as hardly to admit of being handled. The *digestive mucous surface* is softened, injected, ecchymosed, of a dark hue, and sometimes thickened, abraded, or even ulcerated in the lower parts of the canal. The *mesenteric glands* occasionally, and the *pancreas* more rarely, are enlarged or otherwise changed. The *bronchial lining* is generally dark, injected, and soft. The *lungs* are sometimes congested, infiltrated, condensed, or inflamed. The *pleura* and *pericardium* often contain some dark sanguineous serum; and the substance of the *heart* is frequently soft, flaccid, and readily torn, the cavities being occasionally dilated, more especially after the adynamic states of the disease. Adhesions between the pleuræ are rare. The changes within the *cranium* consist chiefly of congestion of the veins of the pia mater and sinuses, with a fluid dark blood; and sometimes of effusion of serum into the ventricles, and between the membranes. But the lesion of the *encephalon* are seldom very great, or in relation to the severity of the cerebral symptoms during life.

243. iii. *DIAGNOSIS.* — It might be supposed that the remissions would be a sufficient characteristic of this fever, and they certainly are so as respects the remitting type. But the occasional occurrence of yellowness of the skin, and of black vomit, in the advanced stages of its more intense forms, has

been the means of confounding it with two other species of fever, in which also yellowness of the skin and black vomitings occur — the *bilio-inflammatory* or *ardent fever*, which attacks only new comers to an inter-tropical country, especially America and Africa — and the *true infectious yellow fever*, which sometimes spreads in a most pestilential form. The more intense and adynamic forms of remittent, the bilio-inflammatory or ardent seasoning fever of Europeans recently arrived in a hot climate, and the true yellow fever arise from different causes, and present different phenomena at their commencement and early course, although the character of the symptoms often approximates in their last stages.

a. 244. As respects the *intense and adynamic states of marsh remittent*, it has been shown above that the exacerbations seldom continue above fourteen or eighteen hours, so that one takes place daily, varying, however, in intensity, so that they thus usually present a quotidian or double tertian type; but in the *bilio-inflammatory, or ardent seasoning fever* of Europeans, the type is continued, or a remission does not occur till after thirty or thirty-six hours, a different train of symptoms then usually appearing. These two fevers arise from different causes; — the *remittent* always proceeds from malaria in some form; hence it is common to all warm countries, and to temperate regions in warm seasons, and varies remarkably in severity; the *bilio-inflammatory or ardent fever* may probably also arise from the same cause, but it is more especially the effect of temperature upon European constitutions, or of atmospheric vicissitudes and other causes acting concurrently with these; hence the much greater uniformity of its character, in which it nearly approximates to the bilio-inflammatory form of the remittent. Whilst remittents can, in every instance, be traced to terrestrial exhalations — to the sources described in the article ENDEMIC INFLUENCES, ardent fever often appears where the operation of such causes has been impossible, and where I have endeavoured in vain to account for its occurrence, excepting in the way stated hereafter.

245. b. These two diseases are the *seasoning fevers of Europeans arrived in a hot climate* — ardent fever commonly appearing in robust plethoric persons who have emigrated to the West Indies, inter-tropical Africa, &c.; the intense forms of remittent, in those less robust, or who have not been attacked by ardent fever, and who have been exposed to malaria after their arrival. This statement is illustrated by the following facts, which came under my own observation in 1817 and 1818: — Some young men arrived from Europe in a place within the tropics, during the healthy season, and where no sources of malaria then existed. They soon were attacked by the common ardent fever, with two or three exceptions, and recovered by means of the treatment advised for this disease; but during the unhealthy season, several of them had remittent fever; and those who had not been attacked by the ardent seasoning, had the more severe forms of remittent, which was their seasoning. In the East Indies, bilio-gastric fever and the inflammatory forms of remittent are the most frequent fevers in recently arrived Europeans; but in the West Indies, ardent fever is the most common, especially in the young, plethoric, or robust — in those much exposed to the sun's rays,

who use great exertion, and live freely or intemperately, who neglect their bowels, or check the perspiration.—In the latter, the yellow skin and vomitings of dark matters are most frequent, and appear earlier than in the intense forms of remittent, and both diseases, although distinct, have been denominated yellow fever, from the contingent appearance of a single symptom, towards their close, and have thereby been confounded not only with each other, but also with another fever distinct from both, and merely because one or at most two symptoms are common to all three, but only in the last stage of the most unfavourable cases.

246. *c. The true or pestilential yellow fever is different from severe remittents and from ardent fever, neither of which is infectious, whilst true yellow fever is eminently infectious.*—*a. Ardent fever* occurs only in Europeans recently arrived in hot climates, and never in the acclimated, nor in aboriginal or native inhabitants: it cannot attack the dark-skinned races, and the assimilated European.—*β. The severe forms of remittent* affect both those who have recently arrived in miasmatic districts, after they have been exposed to endemic causes, and those who have resided longer, and become seasoned or acclimated, especially when the causes have been concentrated or intense. They may also attack individuals from adjoining districts, especially from elevated situations, when they descend to the low grounds, and swamps near the sea, or the embouchures of rivers; but they rarely affect the aboriginal inhabitant, and the negro races.—*γ. The true yellow fever*, on the other hand, attacks the unseasoned, the seasoned, the constant resident, and the dark-skinned races—the negro as well as the European—all within the sphere of its infection who have not previously had the disease. A former attack protects from true yellow fever; but remittents will occur again and again in the same person; and even ardent fever will occur a second time, if the person who has once been affected by it has returned to Europe, resided long in it, and afterwards gone to a warm country; although on this second visit, the fever will much more probably be an inflammatory remittent, than the ardent or bilio-inflammatory disease. The remittent is endemic in warm climates, and in several temperate countries in warm seasons, especially those abounding with the sources of malaria; the ardent fever occurs only among persons who have recently arrived from cold or temperate climates, into a very hot country; and true yellow fever appears only occasionally, and then the infection may either extend to a few only, the circumstances favouring its diffusion not existing, or to great numbers, the disease thereby becoming epidemic. Thus, the first and second of these fevers are always occurring, especially the first; the third, seldom, or after long intervals.

247. The confusion which has thus arisen from confounding three diseases so essentially distinct has been perpetuated by published works and in official returns. Thus a practitioner observes fever in the West Indies among sailors or soldiers lately arrived; and has to treat, although the locality is healthy, a number of cases of ardent fever, with high action at the commencement, and, in some of the most unfavourable of these, with yellowness of the skin, black vomit, &c. in the last stage. He finds large depletions cure

the disease; and notwithstanding his range of observation is confined, and the symptoms referred to contingent, he publishes, to inform all whom it may concern, that he has had numerous cases of yellow fever to treat, that he cured nearly all of them by large bloodlettings, and that the disease was neither contagious nor infectious; all which was very true, with the single exception of the disease being yellow fever, the ardent or bilio-inflammatory, arising from very different causes, having been mistaken for it; and very probably a case of true yellow fever had never come within the sphere of his observation during his residence in the country; or if it has appeared, it has been mistaken for the disease now instanced, or for a severe remittent; or indeed all three may have been confounded together, as most commonly is the case.—A second practitioner arrives in a part of the country where the intense or concentrated states of remittent are endemic, and where it presents the inflammatory, or bilio-inflammatory form, in persons more recently arrived from Europe, and where also yellowness of the skin, &c. occasionally appear in the last stage. He finds that bleeding kills as many as it cures when indiscriminately and incautiously employed, and has therefore recourse to mercurials, especially calomel, observing that, when salivation occurs, the patient is generally safe. He also believes that he has had yellow fever to treat, that it is the endemic of the country, and not infectious, and that mercury given to produce salivation and not bleeding is the cure for it. He writes to convert those who entertain different opinions from himself, and thinks that no one else knows anything of the matter. The same errors are committed in this case in the former, excepting that another disease has been mistaken for yellow fever, although that malady has either never been seen by him, or has been confounded with the endemic of the country.—A third practitioner has enjoyed a more extensive range of observation: he has observed not only both these diseases, but a third also; he has recognised the origin of the three in very different causes; has noticed marked distinctions between them, in their early stages especially; has ascertained the infectious nature and the only occasional occurrence of one of them, to which the name of yellow fever is most applicable; he has watched the beginning, progress, and devastating spread of this malignant disease; and he has experienced the inefficacy of treatment in its most severe cases. These important facts and many others connected with the subject are placed before the public, but are controverted by the first and second practitioners, and those who, having observed, like them, in one confined circle, and during a period of no great duration, have, notwithstanding, become instructors of others; and who, wanting the experience of those whom they oppose, have not even inspiration to plead either in behalf of their doctrines, or as an apology for their intrusion. Thus the inexperienced are bewildered by contrariety of opinions, or misled by partial views which do not apply to the circumstances and diseases which often will present themselves. It will, therefore, be better for him, who has to treat for the first time the fevers thus generally confounded with each other, to apply himself to the task with a mind well instructed in pathological principles and

with a due knowledge of disease and of therapeutical agents, but perfectly unbiassed by doctrine or by the reputed efficacy of certain modes of treatment; otherwise, he may find out, after some untoward experience, that neither the doctrine, nor the practice founded on it, applies to the cases which he is called upon to treat. I never shall forget with what bitterness an amiable physician many years ago told me, on my meeting him in an unhealthy climate within the tropics, where he had arrived some months before myself, of his want of success in treating the fevers of the country. Being desirous of the guidance of those who had written on the disease, he had treated it at first conformably with the instructions given in books, and the first nine cases terminated fatally in rapid succession. The practitioner should observe and think for himself; and whilst his mind is open to the suggestions which works will furnish, he should ascertain the states of vital power, and of local and general morbid action, in each case, and employ medicinal agents appropriately to these, and with promptitude and decision, guided but not weakened by caution.

248. iv. TREATMENT.—*A. Of the mild remittent.*—The treatment of this form differs not materially from that advised above for agues, especially when the remissions are distinct. At the commencement, before reaction is developed, and when there are no indications to forbid their exhibition, *emetics* are generally of great benefit. After their full operation, a large dose of *calomel*, or of *calomel* and opium, may be given, and an action produced on the bowels by *purgatives* and cathartic enemata. These means having been repeated until morbid secretions and faecal accumulations are evacuated, bark or quinine may be prescribed, if the remissions are distinct, and the patient not removed from the unwholesome locality. But in cases where the previous health and long residence of the patient in an unhealthy climate do not forbid it, moderate *bleeding* in the stage of excitement will shorten the disease, and render the remissions more perfect. During reaction in the early exacerbations, repeated doses of *James's powder* with *calomel*, or the *potassio-tartrate of antimony* given in solution every hour or two, or every half hour, in full doses, commencing it in the cold stage, so as to produce vomiting, and continuing it in this manner throughout the subsequent reaction, will frequently accelerate a favourable termination; and render large vascular depletion less necessary. In old residents in warm climates, or in those constantly living in an unhealthy situation, this medicine will often supersede bloodletting, if the bowels are early and freely evacuated. In the mild autumnal remittent, also, of this climate, a similar treatment is appropriate; bleeding being required chiefly in the young, robust, and plethoric. Subsequently, refrigerants, cooling diaphoretics, and other appropriate means may be employed.

249. B. In the *inflammatory and bilic-inflammatory forms*, the practice, early in the disease, should be energetic.—*a.* In the cold stage, or that of invasion, and when, although there may be most severe headach, the heat of the scalp and the action of the carotids indicate that it is not inflammatory nor dependent upon fulness of blood; and when excessive vascular action in the stomach and liver has not yet been developed,

an active *emetic* is of essential service. As soon as the stage of excitement is developed, and proportionately to its excess, and to the degree in which vascular action becomes predominant in the head, liver, or stomach, should *bloodletting*, generally or locally, or both, be practised; the quantity having relation to the constitution, habit of body, &c. of the patient. In order, however, that depletion may be productive of benefit, it must be practised early in the disease; for, if deferred till the excitement has partly exhausted the powers of the system, its good effects cannot then be obtained; the nature of the pathological states admitting of *local depletions* only, which, however, should be employed in order to remove such local congestions as may have taken place.

250. *b.* Full doses of *calomel*, followed by purgatives (F. 181. 216. 266.) and cathartic enemata (F. 140, 141. 150.) are also early requisite; the first of these having been given soon after the operation of the emetic, and combined with *James's powder*. During the vascular excitement, particularly when the skin is very hot and dry, the cerebral symptoms strongly marked, and the abdominal viscera free from congestions, *cold applications* should be kept to the head, and the *cold affusion* frequently resorted to. When vital power is much impaired by the impression of the exciting causes, or exhausted by the previous excitement, and when the abdominal viscera are congested, as evinced by the fulness and tenderness of the hypochondria and epigastrium, the cold affusion is a hazardous measure, the constitutional powers not being always sufficient to bear the shock, and the overloaded viscera sometimes suffering further from the external impression. In such circumstances, especially when the pulse is quick and irritable and the skin harsh, the *tepid bath*, and sponging the surface with cold or tepid water, will be preferable. A certain degree of vital power is necessary to a successful application of the cold affusion; the surface being hot and dry, and the internal viscera not seriously congested.

251. *c.* When the *head* is much affected, *leeches* to the temples, behind the ears, and to the occiput, or cupping, will be serviceable; evaporating lotions, or the cold affusion on the scalp being resorted to: but even these may be injurious if employed too late, or in states of exhaustion. The appearance of the face and eyes, the heat of the scalp, the expression of the countenance, and the action of the carotids should guide the practitioner, and not the degree of delirium or of insane delusion; for these may be most remarkable where vascular action in the brain is lowest, as they depend more upon nervous and cerebral power than upon vascular action. When much heat, pain, tenderness, and fulness of the *epigastrium* or *hypochondria*, with nausea and vomiting, are present; the matters thrown up being viscid or ropy and abundant, and yellow, green, or yellowish green, or dark green, or colourless, and mixed with albuminous flakes, energetic vascular depletion should be early resorted to, otherwise the vital tone of the mucous coat and capillaries of the stomach will be soon exhausted, and dark grumous vomiting supervene. In these cases, a large bloodletting from the arm, and twenty grains of *calomel*, with two or three of opium, should be promptly prescribed. If these be fol-

lowed by marked mitigation of the symptoms and a copious perspiration, this latter should be encouraged by cooling diaphoretics; but if the symptoms continue or return, either a repetition of these remedies, or a large depletion near the seat of the chief disorder, ought to be directed. A large *blister* should be afterwards applied, or the warm *turpentine epithem*. The latter is preferable, inasmuch as its effect is almost immediate, as it excites a copious perspiration, and as it may be renewed from time to time with additional benefit. *Purgatives* may now be given, and they will generally be retained; but those which are least irritating to the stomach should be selected, and their action promoted by cathartic enemata. In the intervals, the liquor ammonia acetatis, with camphor mixture and nitrate of potash, may be prescribed, or other cooling diaphoretics.

252. *d.* If the *bile* be secreted in great quantity and acrid quality, the consequences of the active determination to the liver occasioning this disorder, and the effects of the morbid secretion upon the digestive mucous surface, ought equally to be guarded against, by local depletions, by external derivatives, cooling diluents and demulcents, and by aperient injections. If symptoms of inflammatory action in the *liver* are manifest, the same measures should be promptly and energetically employed. If the *bowels* be inordinately affected, a similar treatment is necessary; the external rubefacients being applied over the abdomen; and a large dose of calomel and opium should immediately follow the depletions. All these ought to be repeated according to circumstances; emollient and laxative medicines being exhibited by the mouth and in enemata, and cooling diaphoretics in the intervals. When soreness, tension, or fulness of the bowels continues notwithstanding, the external applications (§ 251.) should be repeated. If with fulness of the abdomen, there is much load on the tongue, and oppression at the epigastrium, purgatives, especially in enemata, should be persisted in.

253. *e.* The *exhaustion* of the advanced stages, produced by the previous excitement and by the treatment, demands attention. If the above means have removed all local disease along with the morbid excitement, and if the patient is beyond the influence of the causes, little more is necessary, as the system soon rallies. But if he be constantly subjected to them, the consequent exhaustion will be thereby increased, or its character modified, and the adynamic condition superinduced. In such cases, suitable means are devised with great difficulty. If the exhaustion be attended by a distinct remission, the pulse falling in frequency, and the tongue remaining moist, the irritability of the stomach having subsided, the exhibition of bark or quinine should not be delayed; for by it chiefly are we to hope to prevent an accession of the febrile action, and to preserve the powers of life from the noxious influence of the surrounding causes. But the effect of this substance should be carefully watched: as long, however, as the tongue is dry or rough, with the papillæ erect, the pulse hard or irritable, and the skin hot and harsh, the remains or unfavourable consequences of the previous morbid action are still unsubdued; and these the exhibition of bark would increase. In this case, local depletions, tepid or warm bathing,

purgatives, diaphoretics, and external rubefacients are still required. If the symptoms and circumstances of the case warrant the use of bark, the decoction with the carbonate of soda and nitrate of potash, or with the liquor ammonia acetatis and hydro-chlorate of ammonia, may be first employed, and subsequently the more active preparations of this substance; but, during its exhibition, the secretions and excretions must be promoted by purgatives with mercurials, &c. The decoction may be given for this purpose with the neutral purgative salts, or quinine with either of the sulphates, so as to keep the bowels freely open. If calomel has been freely given at the beginning, and the bowels well evacuated in the progress of the disease, blue pill, with the aloes and myrrh pill, and ipecacuanha, may be taken at night, and the bark or quinine in the day. It is chiefly in cases where depletions and purgatives have been too long delayed, or insufficiently prescribed, and where the latter have been laid aside too soon, that the bark either fails, or occasions congestion or obstruction or consecutive inflammation of any of the abdominal viscera.

254. *C.* The *adynamic states* of remittent fever, occurring primarily, or supervening secondarily upon either of the other forms, are the scourges of intertropical countries; and present such a variety of characters in both hemispheres—the yellowness of the skin and dark grumous vomiting, predominating in the western hemisphere (the *Yellow Remittent Fever* of Dr. СИНШОЛМ)—that methods of cure which shall be appropriate to their varying forms are often devised with as great difficulty as with want of success. In every condition, however, the removal of morbid secretions and accumulations from the prima via is a necessary preliminary. At the period of invasion, the sense of cold being prolonged, and the nausea not attended by free vomiting, and more especially if the formative stage be characterised by dysenteric symptoms, as sometimes observed in hot climates, the exhibition of an *emetic* will be useful.—*a.* In the more malignant states of this form, in which the stage of excitement commences with tumultuous vascular reaction concentrated chiefly in the viscera of the large cavities, and principally in those of the abdomen, *bloodletting*, either general or local, or both, should be practised early in this stage, especially in persons of a robust, plethoric, and sanguine constitution; for, if this state of reaction be not speedily moderated, the vital tone of the viscera which chiefly experience it is soon exhausted, and collapse of the vital powers, with organic change and yellowish discolouration of the skin, supervenes as early as the third, fourth, fifth, or sixth days, in unfavourable cases, and later in those which are less so, followed soon after by dark, grumous vomitings, and all the symptoms to which the term malignant may be appropriately given. Emetics are beneficial only in the formative and invading stages of these cases, and are hurtful if administered in the irritated and inflated states of the stomach and liver generally attending reaction. After free depletion, from ten to twenty grains of calomel should be exhibited, with one or two of opium, and be repeated according to the effect and the circumstances of the case. If the first bleeding has been insufficient, a second should be directed within twelve

or eighteen hours, and followed by the calomel and opium; and the bowels ought to be freely opened. In the worst forms of marsh fever, particularly in hot climates, the secretions of the liver are often interrupted or suppressed, large doses of calomel and active purgatives being especially required in them. If the mouth become affected, the circumstance is favourable, although we should hardly make this a specific indication unless other intentions be also fulfilled. The warm bath, followed by frictions of the surface, or by the terebinthinated epithem on the abdomen, and by diaphoretics, will also be of great service.

255. *b.* Whilst vascular depletions are thus necessary in the more concentrated and inflammatory states, which rapidly pass into the adynamic or malignant form, they are inapplicable to those in which the powers of the system are insufficient to produce vascular reaction; at least, they should never be employed until efforts at reaction are made, when a small or moderate general or local bleeding may be directed, especially after the warm or vapour bath and frictions of the surface, with the view of relieving the overloaded vessels of the large viscera, and of removing congestion of the venous trunks and auricles of the heart. If an adynamic state has continued from the commencement, the skin of the trunk being harsh and dry, the extremities damp, the pulse weak and rapid or irregular, the tongue dark and coated, the bowels disordered or costive, and the evacuations morbid, the vital energies of the frame should be roused by means of the hot or vapour bath; by assiduous frictions with stimulating liniments (F. 299, 300, 311.); and internal congestions removed by warm diaphoretics, stimulants, purgatives, and mustard poultices, or the hot turpentine epithem applied over the epigastrium and hypochondria, and, in extreme cases, on the insides of the thighs also. In this latter class of cases, calomel is still indicated, especially if the stomach be irritable; but it should be conjoined with large doses of either camphor, ammonia, or capsicum, with opium. Subsequently, the bowels having been very freely evacuated, and the states of the tongue, of the pulse, and of the skin not forbidding, bark in decoction, or sulphate of quinine, may be prescribed.

256. *c.* A similar treatment is indicated when an adynamic or malignant state supervenes on that of low excitement — when the skin becomes yellowish or dusky, and the irritability of the stomach urgent or disposed to pass into the dark grumous vomitings, indicating great danger. This affection of the stomach is much more violent when it is consequent upon excitement than when it occurs in the course of a fever in which excitement has been imperfectly expressed; for, in the former case, the vital power of the organ is exhausted, and the organisation affected; in the latter, power is simply diminished or suppressed, restoration being more easy in it than in the former. In both circumstances, the external derivatives just mentioned, and calomel in the combinations specified, are chiefly to be relied upon. When the vomiting consists of a pumping up of the contents of the stomach, rather than of active retchings, cordial stimulants should be employed in addition to these; and aromatic spices, am-

monia, ether, camphor, opium, &c., may be variously combined. Fluids evolving carbonic acid, as spruce beer, seltzer-water, soda-water, bottled stout, &c., may also be prescribed. In a few urgent cases, I have found from half an ounce to an ounce of the spirits of turpentine, taken on the surface of milk or any aromatic water, with half a drachm of magnesia, allay the irritability of the stomach, lower the pulse, and render the tongue moist, after other measures had failed; and I have exhibited this dose, or F. 216., as a purgative, three or four hours after a bolus consisting of ten or fifteen grains of camphor and calomel, with one, two, or three of opium, had been taken; promoting the action of the bowels by warm cathartic enemata, if necessary.

257. *d.* In low, miasmatic districts, bark or quinine, in suitable combinations, is often necessary in an advanced stage of the adynamic states. The former in substance, however, or the latter in large doses, generally irritates the stomach, and it then proves injurious. The infusion of bark, therefore, with the chlorate of potash, or with hydrochloric acid or ether; or the decoction with hydrochlorate of ammonia, or with nitrate of potash, and the solution of the acetate of ammonia; should be first employed; and subsequently, the quinine with acids. But while we thus endeavour to support vital power, morbid secretions and faecal collections should be fully evacuated, either by mild purgative draughts, — and preferably by those of a stomachic or tonic kind, — or by enemata, or by both. If the combination of the mild preparations of bark with the antiseptics and refrigerants just instanced are inefficacious, the more energetic preparations with ether, or the preparation of ammonia, or with aromatics, &c. must be resorted to.

258. *D.* The complicated states must be treated with reference chiefly to the condition in which vascular action and vital power are manifested. The treatment of the more inflammatory complications has been already described. The complications of the more adynamic states are so diversified, that the measures already recommended, as well as others about to be noticed, must be adapted to individual circumstances. If an irritable or dysenteric state of the bowels occur, morbid secretions or faecal accumulations have probably caused irritation of the mucous coat. A full dose of calomel should therefore be given, if it have been neglected, and be followed by a common purging draught, by castor oil, or F. 181. 216. 266.; and, in a few hours, laxative enemata, and demulcents should also be administered. After the full operation of these, anodynes, with gentle alteratives and light tonics, or the preparations of bark or quinine in the forms above mentioned, may be exhibited. In the adynamic states, this complication is very unfavourable, especially when the stools are very dark, black, or otherwise morbid; and the abdomen swollen and painful. Calomel, with camphor and opium, is necessary in such; and large blisters, or the other external applications previously directed (§ 251.), are especially indicated. Tonic purgatives, &c. are also requisite; and bark or quinine in large doses, and in forms of combination most appropriate to this particular class of cases. The other complications either have been already noticed, or demand no material modification of the treatment. Whether seated in the head, thorax, or abdomen, the state

of vascular action, in connection with vital power, requires attention; local depletions, external derivatives and revulsants, active purgatives and diaphoretics, with diuretics, constituting the chief means of cure.

259. *E.* A treatment has been strongly recommended by Dr. STEVENS for the advanced stages, and malignant or adynamic forms, of remittent and other fevers; but I am not aware that it has been satisfactorily or properly employed by other practitioners. One of the substances, at least,—the chlorate, or oxymuriate of potash,—I have often prescribed as a tonic and stimulant, and for a great many years, both at the infirmary for children, and in private practice; and I am quite convinced, from an extensive experience of its effects in low states of fever, of its very beneficial effects. It has often a remarkable and rapid effect upon the state of the tongue, rendering it more moist and clean. Dr. STEVENS state that, when adynamic symptoms appear, after venesection, mercurials, cold affusion, and purgatives have been prescribed, no time should be lost in exhibiting non-purgative saline medicines, especially the carbonate of soda, the chlorate of potash, and common salt; and that these should be repeated every hour during the disease. These substances he believes to act beneficially upon the constitution of the circulating fluids, and to replace that portion of the saline constituents of the blood, which he supposes to be lost or changed in the early course of the disease.

260. *F.* If the remissions become hardly distinguishable, the states of morbid action being in other respects as above treated of, the method of cure must still be the same as recommended for the inflammatory, bilious, concentrated, and adynamic or malignant forms respectively; the nature of the disease being no further changed by the continued type thus assumed, than that the constitution suffers more decidedly, and the vital powers sink more rapidly under the unremitting state of disease induced. Hence the means of cure should be the same in kind, but administered, in warm climates especially, with greater promptitude and decision.

261. *G.* Where remittents assume the intermittent type, as they occasionally do in unhealthy localities, the liver, spleen, or mesenteric glands, or all of them, are more or less disordered, or actually diseased; and enlargement or obstruction of one or more of them generally soon afterwards becomes evident. In cases of this kind, although the active exhibition of bark or quinine is necessary to prevent the return of the paroxysms, which, by their continuance, would increase the mischief, yet the full operation of purgatives and deobstruent laxatives is equally requisite; for, without them, neither will the obstructions already existing be removed, nor the intermittent disease be safely arrested, nor the bark or quinine exhibited with permanent advantage to the patient. In cases of this kind, change of air is next in importance to the employment of suitable medical treatment; and, in all cases, the one should accompany the other. If remittents pass into dysentery, disease of the liver, and of the mesenteric glands, with the other changes in the large bowels, fully described in that article is a common pathological state; and the treatment must be directed accordingly, and as fully detailed under the above

head. The regimen and convalescence of the patient, and the means proper for the prevention of relapses, differ in no respect from what has been stated on these topics under the treatment of intermittents (§ 223, 224.).

XIII. CHRONIC OR OBSCURE REMITTENT. SYN.—Anomalous or relapsing Remittent; Slight Nervous Fever, I. MACCULLOCH.

262. CHARACT.—Slight febrile exacerbations and remissions, with headach, &c.; recurring in daily, occasionally in reduplicating, paroxysms; continuing for an indefinite period, and giving rise to various disorders of the digestive organs and nervous system.

263. This very slight form of remitting fever often continues a very long time when its nature is mistaken. It is by no means an infrequent disease: three or four instances of it have been treated by me very lately; and before my attention was directed to it by the writings of Dr. MACCULLOCH, other cases had disappointed my anticipations as to their nature and treatment. It appears in delicate persons, and commonly arises from the less energetic action of the same causes which produce the more decided and acute forms of marsh fever, and generally in a primary mode; but it also may follow the simple remittent described above. It bears the same relation to the definite and severe disease, as the slight, anomalous, or masked intermittent does to regular ague. When it is so marked as to be esteemed a fever, it is often mistaken for hectic; and in its slighter modes it is confounded with what is commonly called debility, chronic debility, chronic dyspepsia, delicate health, nervousness, low spirits, hypochondriasis.

264. *A.* In the cases which have occurred to me, exposure to malaria was manifest; and to two patients the cause was assigned and explained, and a different residence recommended. Whether it may arise from other sources, is not determined; but I entirely agree with Dr. MACCULLOCH in believing that malaria is far oftener present than has been imagined, more especially during late years, and around the metropolis. In those cases which have been traced to this source, the whole character of the disorder is that of remittents, as shown by its tendency to critical periods, and its diurnal remission, &c. It often, also, terminates in an intermittent as slight and obscure as the original disease; while it is not infrequently followed by local affection of the nervous system, especially periodical headach, toothach, intermitting rheumatism, and neuralgic pains. Its frequent recurrence or relapses, especially during north-east or easterly winds, and in the outskirts of the metropolis, thereby resembling anomalous or masked ague, is also a circumstance deserving of remark, and an argument for considering it, with Dr. MACCULLOCH, as a modification of remittent, and as the effect of a slighter dose or different conditions of the marsh poison. By mistaking this fever for other diseases, the sufferings of the patient are often materially aggravated; whilst, having recognised its nature and cause, not only the means of cure, but also those of prevention become obvious. In many cases the cure and prevention are accidentally hit upon either by the practitioner or patient; and the state of ill health complained of removed by change of air, or a visit to a watering-place.

265. *B.* The symptoms consist chiefly of great muscular weakness, which often appears unaccountable, of sinking sensations, and disinclination to exertion. A slight chill is often present in the forenoon, or about midday, or a creeping cold down the spine. During the afternoon, evening, and night, a slight degree of febrile excitement is manifest, and the palms of the hands become hot or burning. The tongue is generally white, and the apex and edges are often somewhat red. The urine is often pale and abundant in the morning, and higher coloured, and more frequently voided, in the evening and night. The patient is sometimes unable to follow his occupations in the morning; he wakens unrefreshed, either from a feverish, restless, or disturbed sleep, or from a lethargic, dreamy, and prolonged sleep; he is fatigued all morning, without knowing wherefore; is depressed, anxious, and irritable; or complains of want of mental energy or ability, and of dull headach; and, as the chills and sinkings of this period pass into a gentle febrile excitement, he feels more restored in the afternoon or evening. In the case of a delicate, most talented, and accomplished female, subject to this disease, and liable to relapses of it during cold easterly winds, although the most distressing, sinking, and exhaustion were often felt in the morning, so that she was hardly able to dress herself, or to get up to breakfast; yet she often could in the evening exert and enjoy herself. The pulse is occasionally not materially disturbed: it is frequently accelerated and a little hard, in the course of the exacerbations, but is commonly weak and slow in the remissions. The bowels are generally sluggish; the evacuations slightly disordered; and the appetite, when the heat is considerable, and the exacerbations very marked, is much diminished, and generally capricious. The patient loses flesh during the attacks, and various anomalous symptoms referrible to the stomach, bowels, and other abdominal viscera, often present themselves; and, when they become prominent, are liable to be considered and treated as the original complaint.

266. In many cases, although these ailments are both real and distressing, the patient is considered as either feigning, or hypochondriacal. In these more especially, and when the course of the complaint is less regular, the time of the day when the exacerbations and remissions occur, varies much. If they are tolerably regular, they often present a quotidian, tertian, or double tertian character, the symptoms being worse on alternate days. In the more chronic cases, the mind becomes irritable or despondent, and in some instances this latter feeling is most distressing. Dr. ELLIOTSON confirms the remark of Dr. MACCULLOCH, that the exacerbations are often unobserved from occurring in the night; increased heat, oppression of the head, and depression of spirits, amounting to hypochondriasis, being the chief symptoms. The nights are frequently the periods of greatest suffering. A gentleman, who consulted me in the summer of 1834, described them as being most distressing. In another case, an inability to think, with confusion of ideas, was complained of; an inflammatory dyspepsia, a burning sensation at the stomach, and other symptoms of irritation of the digestive mucous surface; sponginess of the gums, and soreness of the tongue, which often becomes

smooth and divested of its papillæ, occasionally appear in the advanced course of the disease; and ultimately serious disorder of the abdominal organs, prostration of organic nervous power, and a state of ill health, amounting to general disease, supervene.

267. In some instances, this complaint assumes more of the intermitent character, and at different times it seems to vacillate between the remittent and intermitent types; but there is rarely any distinct cold stage or a greater feeling of cold than that above mentioned (§ 265.), excepting at the commencement of an attack, or of a relapse. Signs of functional disorder of the liver, and of torpid function of the colon, often appear, especially in this class of cases; and the disease is frequently considered a form of liver complaint; the heavy or dull headach sometimes attending it being imputed either to the same source, or to the accompanying affection of the stomach.

268. In conclusion, Dr. MACCULLOCH describes this form of remittent as modified chiefly in degree and duration, it being often so slight as to require some attention in tracing its form, and even its existence. It is apt to become habitual, or to recur at frequent but variable intervals, during even an indefinite course of many years; varying in such a course its characters and symptoms, and being in some cases a marked chronic intermitent, in others remittent, and in some so brief and imperfect in its remissions as to be almost continued. Its accessions are of the ordinary duration of remittents, and they commonly observe the quotidian or double tertian periods. It is, moreover, often a primary disease: sometimes it is consequent upon ague, or the severe states of remittent, or even upon continued fever; and, whilst it is especially caused by malaria, in some of the slighter modes of this poison, it may possibly arise from other sources; or, after a first attack, a relapse may be caused by cold, moisture, atmospheric vicissitudes, the use of cold or drastic purgatives, vicissitudes of temperature, intemperance, bloodletting, and excessive evacuations.

269. TREATMENT.—*a.* The slighter, primary, and more recent states of this complaint are removed by the sulphate of quinine, the preparations of bark combined appropriately to particular cases, by FOWLER'S solution of arsenic and change of air; the bowels being duly regulated by laxatives, or mild purgatives combined with bitter tonics (F. 266. 562. 572.) But the more chronic states, especially when the nervous system is much affected and the patient has become despondent and hypochondriacal, are treated with much less success. If it degenerate into confirmed hypochondriasis, the case is one of the most difficult that comes before the practitioner. In some instances an active exhibition of *sulphate of quinine* is of great benefit. Dr. ELLIOTSON alludes to a case in which five grains were given three times a day without benefit; but the dose having been increased to ten grains, relief was procured. When signs of inflammatory irritation of the digestive canal exist, the decoction of bark should be first employed with the nitrate of potash, or with the hydrochlorate of ammonia; and if the tongue be flabby, and the gums spongy, as in the case above alluded to, the decoction may be given with hydrochloric acid, or with the nitro hydrochloric, or with the *chlorate of potash*. The combination of

aloes, or the aloes and myrrh pill, with sulphate of quinine and inspissated ox-gall, will be found the most successful purgative: it proved so in one of the cases I lately treated. The *kreosote* was employed by me in another case, in conjunction with quinine, in doses of from one to four drops three times a day. The patient was much benefited, but went on the Continent soon afterwards.

269. *b. Early change to a dry and wholesome air*, whenever the patient's residence is at all in fault, is the chief part of the treatment. Without this, relapses will be frequent. Healthy watering-places, travelling, and the rest of the means directed in *hypochondriasis*, must be resorted to when the disease has proceeded so far as to be attended by despondency. *Sea-voyaging*, which generally proves so beneficial to persons recovering from the remittents of warm countries, is also very serviceable in this complaint. It is a much more safe mode of enjoying change of air than that too often adopted by patients of this kind; for many of them, preferring to travel on the Continent, are in numerous places and on many occasions much more exposed to the efficient cause of the disease than if they had remained in England. Indeed, the worst instances which I have seen, or which I have heard, have been those who had experienced attacks of ague or of remittent fever in Italy and in warm countries; and, on their return to this country, had suffered from the slighter causes occurring in it, or from the east winds of spring, and then blamed the climate of England for a disease which, if not contracted, had at least its seed sown, in the countries which have been objects not only of their preference, but of their enlogies.

XIV. REMITTENT OF CHILDREN. SYN.—*Infantile Remittent Fever*, BUTTER; *Febris verminosa*, of various authors; *Spurious Worm Fever*, MUSGRAVE; *Febris mucosa verminosa*, GOËLIS; *Hectica Infantilis*, SAUVAGES; *Febris lenta*, HOFFMANN.

270. CHARACTER.—*Exacerbations and remissions, of fever in children, with loaded tongue, loss of appetite and flesh, unnatural evacuations, pains in the abdomen and head, and much irritability; generally chronic in its duration.*

271. *i. REMOTE CAUSES.*—This disease usually affects children from nine or ten months to twelve or thirteen years old. It was very generally imputed by writers in the three last centuries to worms, which are rather a complication than a cause of the complaint; but a complication of remarkable frequency on the Continent, particularly in the unhealthy localities where this affection is most common, and often misunderstood; both this complaint and worms in the *prima via*, being occasionally concomitant effects of one and the same cause, which has been very generally overlooked. The remarks of HOFFMANN, BAGLIVI, DE HAEN, BRERA, and GOËLIS, as to the influence of the latter disorder in causing the phenomena of infantile remittent, should, therefore, be considered merely as proofs of the frequency of this concomitancy; whilst our experience of the disease, in this country in particular, demonstrates its independent nature. Dr. MUSGRAVE, in his "*Essay on the Worm Fever*," was the first who distinctly stated this; but a nearly similar opinion had been given by Professor SINCLAIR, of Edinburgh, long previously, and had also been

entertained by Dr. MUSGRAVE's contemporary, Dr. WILLIAM HUNTER. Dr. CLARK confirmed the statement of MUSGRAVE; and the subject was soon afterwards set at rest by the publication of Dr. BUTTER's work on the "*Infantile Remittent Fever*."

272. Dr. BUTTER assigned debility of the digestive organs, errors in diet, accumulations of morbid matter on the *prima via*, and the peculiar irritability of childhood and proneness to fever, as the principal causes of the complaint. I believe it to be often caused by improper food, by collections of mucous sordes in the digestive canal, owing to a neglect of the bowels; and by too cold or thin clothing; in connection with debility of constitution, and morbid irritability of the frame. But, having observed it most commonly in situations evidently productive of humid exhalations; in low, cold, and moist localities; and after exposure to a cold air after rain, particularly at night or in the morning, or during easterly winds; I am led to infer that it arises most frequently from the same causes as produce other periodic fevers; namely, terrestrial exhalations, or miasmata, and that less intense or concentrated states of these exhalations, than are required to produce either agues or remittents in adults, will often occasion the latter in children.

273. *ii. DESCRIPTION.*—This complaint usually commences gradually; the bowels being irregular, generally costive, but sometimes relaxed or irritated. Febrile exacerbations, with drowsiness, occur in the course of the day and evening, the child often evincing little disorder during the remission, excepting a loaded tongue and peevishness. The pulse varies in frequency with the exacerbations, and ranges from 100 to 140. The appetite is variable. These are often the chief symptoms of several days, when the complaint becomes aggravated, and a distinct chill or rigor is sometimes observed; followed by vomiting, and a more violent paroxysm of fever, drowsiness, flushed cheeks, and shooting pains through the abdomen and head. The child constantly picks its lips, nose, and eyes; and even pushes substances up the nostrils; and occasionally stiffness of the neck, great sensibility of the general surface, and tenderness, in the course of the spine, are observed. After some time, the functions of the digestive canal are almost entirely destroyed, the *ingesta* being either thrown off unchanged, or passed undigested from the bowels. In older children, the evening or night exacerbations are often attended by delirium. In some instances, particularly in very young children, convulsions occur, and render the diagnosis a matter of difficulty, unless the patient be carefully observed during the remissions. Such is the most common form this complaint assumes. Dr. BUTTER has, however, distinguished three varieties, which he has denominated the *acute*, the *slow*, and the *low*. There are some grounds for this division; or, rather, the complaint presents numerous modifications, which may be arranged under these or similar heads.

274. *A. The acute variety* is generally preceded by symptoms of indisposition, but it may occur rather suddenly. The bowels are irregular—commonly costive; the evacuations are morbid and offensive; the urine turbid, pale, or milky; and the tongue is loaded, especially at

the root. Fever supervenes, and is ushered in by cold, rigors, or chills; the child being hot and restless at night. The febrile exacerbations generally recur in the afternoon, and during the night; but there are often three fits, one also occurring in the forenoon; and, in the most severe cases, the remissions are very indistinct. During the *exacerbations*, the child is drowsy; and, if it sleeps, starting, moaning, and even screaming, or incoherence, are observed; sometimes with vomiting, flatulent distension of the abdomen, accelerated respiration, and cough. The pulse varies from 120 to 160, according to the age. The cheeks are usually flushed; the abdomen and palms of the hands being hotter than other parts of the body. Occasionally, the paroxysm terminates in a slight perspiration, which is often partial; the child falls into a quiet sleep, and the pulse sinks in frequency. During the *remissions* he picks his lips or nose; is irritable, and without appetite. The bowels are acted upon with difficulty; the evacuations are generally unnatural, but present no constant character; and worms are occasionally voided. The urine is now transparent, of an orange colour, and its quantity in relation to the fluids taken; and all the other symptoms noticed above are present in an aggravated form. As the disease declines, the exacerbations become mild and short, and often terminate in a gentle perspiration, with a sound or refreshing sleep; the urine deposits a sediment, and is pale; the appetite returns; and the stools assume a healthy aspect. But the pulse remains frequent, and the flesh and strength are regained very slowly, unless change to a mild dry air is adopted. If this form of the disease be either neglected, or improperly treated, or if the child remain in a moist or miasmatic situation, organic change, in some important organ supervenes; or the complaint passes into the chronic form, hereafter to be described; or degenerates into marasmus from mesenteric disease. It usually terminates in from two to four weeks in the more favourable cases.

275. *B. The more adynamic variety*, or state of the complaint, is the least common; excepting in low, humid, and miasmatic situations. It is sometimes prevalent at the same season with the **CHOLERIC FEVER OF INFANTS** (see this article), evidently depends upon the same causes as it, and is a very closely allied complaint, differing from it merely in the type of the fever, and the degree in which the digestive canal is affected. This variety commonly begins more suddenly than the others; the earlier exacerbation being attended by the same symptoms as the preceding, but by greater affection of the head, and by delirium in the older children; and quickly passing into more or less exhaustion. When this change takes place, the child becomes quiet, or indifferent to external objects, and indisposed to the least exertion. He dozes, and is incoherent in the exacerbations; and, in the remissions, he lies in one position, contantly picking his face, particularly his lips and nose, until they become sore; or keeping his hands in continual motion. He usually, however, takes both food and drink, although sparingly. The countenance is anxious, pale, and unhealthy; the eyes reddish, especially the edges of the eyelids; the lips are covered with dark, ragged crusts, or exfoliations of their

epithelium; the tongue and teeth are loaded with dark sordes; the bowels are much disordered—often irritable; and the stools are very offensive, watery, greenish, or otherwise morbid, and preceded by much griping and flatulence; both the stools and the urine are frequently passed involuntarily. When a favourable change takes place, the symptoms gradually subside; the voice, which was nearly lost, is regained or becomes stronger; the eyes are more lively; the tongue is cleaner, and the evacuations improve; the exacerbations being shorter, and the remissions more perfect and prolonged. This variety is generally more chronic than the preceding, but less so than the next. It usually continues from one to two months.

276. *C. The chronic form of remittent* in children either makes its approach gradually and insidiously, or follows the acute. The child wastes; the abdomen enlarges; the breath is offensive, and the strength fails. There is commonly only one exacerbation in the twenty-four hours, and it seldom appears before evening, lasting till morning, and terminating in sweats. The pulse is usually about 100 in the day, but rises to 140 in the evening. The tongue is white or loaded, but moist, and has often a strawberry appearance; the bowels are generally costive, and the stools always morbid. The child commonly keeps up, but is disinclined to move, or complains of aching in the limbs on exertion. There is little or no appetite or thirst; and the other phenomena characterising the complaint, in its common form, are present in various grades of severity. If the disease is not removed, tympanitic distension of the abdomen, emaciation, harsh discolouration of the skin, enlarged mesenteric glands, apthous sores on the lips and tongue, chronic diarrhoea, and lenterly supervene. When the disease declines, all the symptoms gradually amend; the nocturnal exacerbations abate; and convalescence is established after a period varying from two to four or five months.

277. This disease is generally sporadic, but is also sometimes epidemic. It is endemic in unhealthy localities; and many of the children born of European parents in hot or unhealthy climates are cut off by it before they reach their sixth or seventh year. When it occurs epidemically, it usually assumes the first or second of the above forms; and proves both more rapid in its course, and more dangerous, than in the ordinary states.—Dr. SIMS, after describing the fevers prevalent in London in the years 1769 and 1770, which seemed chiefly to result from the endemic sources surrounding the metropolis and the state of the seasons, gives a very graphic account of this complaint, as it appeared epidemically during these years, and simultaneously with these fevers. As his description very nearly represents the disease as I have seen it in very low and miasmatic situations, I shall abridge it at this place. He remarks, that it was called by some a worm fever, though worms were seldom the cause; but as that apparently lay in the stomach and intestines, the error did not materially affect the practice. It was most common in children of a sallow complexion and thin habit, who had been over-fed, with the mistaken view of supporting and nourishing them.—The leading symptoms were, heat, thirst, quick, full pulse, vomiting, coma, and sometimes slight convulsions,

an universal soreness to the touch; a troublesome phlegmy cough, and great peevishness when not comatose. The fever was constantly of the remittent kind, the cheeks often appearing highly flushed, at other times pale. It lasted for several days, but seldom beyond a week; nor was the fatality attending it very considerable. Many of those who were seized by it had been subject for some time to symptoms which are thought to point out the existence of worms in the *prima via*, as picking of the nose, grinding the teeth, starting out of sleep, swelling of the belly, white urine, short dry cough, &c.; yet worms scarcely ever appeared. These symptoms were evidently, as stated above, the early stage of the complaint — those described by Dr. SIMS its fully developed state.

278. iii. DIAGNOSIS. — This complaint is most liable to be mistaken for *hydrocephalus*, in its acute or subacute forms. Dr. PEMBERTON has pointed out the differences between them with tolerable accuracy. In the latter, there are occasional screamings in the sleep, tossings of the hands above the head, continual endeavour to thrust the head backwards, and an intolerance of light, with more or less strabismus. But in this fever there is seldom screaming or intolerance of light, and never strabismus; the hands being brought to the head merely to pick the lips and nose. In *hydrocephalus* the faculties are totally destroyed, and the patient cannot be roused to an exertion of sense, reason, or even of consciousness. But in the delirium of this fever, he can be at any time recalled to his senses, which he will often retain for a few minutes. In the former, food, or any thing given, however nauseous, will be taken; but in the latter, often neither food nor medicine is taken. The stools in this disease are more easily procured, more curdled, and contain more shreds of coagulable lymph than in *hydrocephalus*. Convulsions seldom occur, excepting at the commencement of the disease; or at its invasion; and when they disappear, the faculties are perfectly restored.

279. Dr. SIMS considers that there is the utmost difficulty in distinguishing between both these diseases, in children under five or six years of age, until *hydrocephalus* has proceeded to the second stage. There is much truth in this, especially where symptoms of cerebral irritation coexist with those of disease of the digestive mucous surface, in the infantile remittent, as is sometimes the case, and as I have several times observed. Yet, in most instances, this disease may be distinguished from *hydrocephalus* with considerable certainty: more particularly by the remissions; by the absence of distinct stages; by its prolonged course; by its affecting delicate, phlegmatic, and over-fed children; by the pains in the belly and head being indistinct, dull, or but little complained of; by the paleness of countenance and sluggishness of manner; by the heaviness and soundness of the sleep; by the perspirations after the exacerbations, and after eating and drinking; by the free state of the excretions, especially the urinary; and the comparative ease with which stools are procured; by the perfect condition of the senses, and tolerance of light; by the unceasing itching of the nose; by the rare occurrence of vomiting; by the little wasting of the body, and the fulness or flatulent state of the abdomen; by the absence of palsy of

any part: by the constant peevishness; and by the absence of any expression of pain or distress of countenance. — (See also *DROPSY of the Head*, § 246.)

280. iv. TERMINATIONS AND PROGNOSIS. — The most common *termination* of this complaint is a return of the healthy functions; but, owing to original fault of constitution, to great debility, to the influence of an impure air, to improper diet, to injudicious treatment, and to neglect, obstruction and enlargement of the mesenteric glands, henteric diarrhœa, chronic hydrocephalus, and tubercular disease of the lungs may supervene. The *prognosis* is, however, favourable when the child comes early under treatment; and more especially if the symptoms subside, and the remissions are prolonged and distinct. An unfavourable prognosis should be formed only when the disease is not benefited by the use of suitable remedies; when the exacerbations become severe, more frequent, or prolonged; when the abdomen is tense and swollen; and when indications of any of the organic diseases just mentioned appear.

281. v. THE NATURE of infantile remittent fever may be inferred from the causes producing it, the circumstances in which it appears, and the early or premonitory symptoms. These indicate impaired organic nervous power, and imperfect performance of the functions actuated by the organic nervous system. Most recent writers have imputed this complaint either to derangement of the digestive canal, or to a depraved condition of the secretions of this part — which amounts to the same thing. The French pathologists view it as symptomatic of inflammation of the digestive mucous surface: but of the truth of this doctrine there is no conclusive evidence. *Post-mortem* appearances certainly lend it no support. The few instances in which I have observed them, presented chiefly enlargement of the mesenteric glands and of the spleen, with a few tubercles in the lungs. The digestive organs were not inflamed; but the intestines were distended by flatus, and their coats attenuated. Similar changes of the bowels and mesenteric glands have been remarked by HOFFMANN and PEMBERTON. From an extensive experience of this disease, I infer — *a.* That it proceeds from causes which impair the energy of the organic nervous system, and of the organs which this system more immediately actuates; — *b.* That, in consequence of this morbid condition, whether it arise from impure air, or proceed from unwholesome food, the excreting functions, particularly those of the digestive canal, are imperfectly performed; consequently mucous sordes, &c. accumulate on its internal surface, and become both a source of irritation and a nidus for the generation of worms; and hence the complication of this complaint with the vermination occasionally takes place; — *c.* That the disease is frequently long in forming, preliminary changes being required, as in other fevers, to develope the more acute symptoms; — *d.* That it does not consist of inflammation, is shown by the character of its early symptoms; by its course, termination, and consequences; and by the *juvantia and ladentia*; — *e.* That it does not altogether arise from a depraved state of secretions of the digestive organs, nor from irritation of these organs, although these changes are very probably induced in its early course, is

proved by the facts that such depravation must itself proceed from anterior disorder, and that a treatment based solely upon the above doctrine is not generally successful; a free and healthy state of the alvine evacuations being often brought about without the complaint being removed; — *f.* That, in order to cure the complaint with the least delay and the greatest certainty, it is necessary to evacuate morbid secretions from the *prima via*, to impart energy to the organic nervous system, and to change the morbid states of the various related or dependent organs.

282. *vi.* TREATMENT. — *A.* The practice advised by MUSGRAVE, BUTLER, SIMS, PEMBERTON, and others, although furnishing valuable hints, is more or less defective; for, whoever trusts to it alone, or those whose resources extend no further, will occasionally find the disease by no means so easily managed as they expected, and will see it prolonged until the treatment is taken out of their hands, and, by the common sense of the parent, limited to change of air, and light nourishment; which, although amongst the most efficient remedies, have been very generally overlooked by writers. In all cases the treatment should be commenced with a moderate dose of *calomel* and *James's powder* at night, and a sufficient quantity of the bitter aperient mixture (F. 266.) or of *rhubarb* and sulphate of potash, or of *rhubarb* and *magnesia*, to act upon the bowels. If these are inefficient, an enema should be thrown up; and from an experience of many hundred cases, I would recommend for this purpose equal quantities of castor oil and spirits of turpentine in water-gruel. At first, the above powder should be repeated every night, or on alternate nights, and the purgative in the morning, the injection being also employed every third or fourth day. At a more advanced stage of the treatment, and when the evacuations have improved, they may be prescribed less frequently. The choice of other means must depend upon the peculiar features of the case.

283. *B.* If the disease be of the form in which it usually presents itself (§ 273.), and the evacuations have been improved by the above means, an *infusion of cinchona*, or of *cascarilla*, or of *valerian*, with liquor ammoniæ acetatis, will be found of great service. If the bowels be still disordered and torpid, the *sulphate of quinine* may be given in a solution of any of the neutral sulphates; and the abdomen rubbed assiduously with a warm *stimulating liniment* (F. 311.), light nourishing diet, or a course of ass's milk, and change of air, being afterwards ordered.

284. *C.* If the complaint be of the acute form (§ 274.), and the child be plethoric and strong, a few *leeches* may be placed over the epigastrium at the commencement of the treatment, and afterwards a mustard poultice, or any *rubefacient epithem* may be applied; but the purgatives just mentioned, or similar medicines, should be prescribed; and the solution of acetate of ammonia with sweet almond emulsion, and camphor mixture, should be taken in the course of the day. After the more acute symptoms have abated, the infusion or decoction of *cinchona*, or the infusion of *cascarilla*, or of *calumba*, may be given with small doses of liquor potassæ, or of the hydrochlorate of ammonia, or the nitrate of potash, or with liquor ammoniæ acetatis, sweet spirits of nitre, &c.

285. *D.* When the disease assumes the adynamic state, above described (§ 275.), and when it has been of long standing, or considerable exhaustion has supervened, a further modification of the treatment is requisite. If the bowels have not been sufficiently evacuated, the above means should be employed for the purpose; and either the sulphate of quinine, or the preparations of bark, or of other tonics, especially *cascarilla*, ought to be taken during the remissions. In all the varieties of the complaint the remissions should be selected for the exhibition of bark, quinine, or other tonics, commencing at the subsidence of the exacerbation. In this state of the complaint, I have prescribed, for many years, the *chlorate of potash* in an infusion of *valerian*, or of *cinchona*, with great benefit, keeping the bowels moderately open, and directing the above liniment (F. 311.) to be rubbed along the spine, or over the abdomen.

286. *E.* When much pain is felt, and the belly becomes distended with flatus, the enema advised above should be administered; and either an anodyne fomentation applied to the abdomen, or the liniment rubbed upon it. MUSGRAVE recommends poultices, or *fomentations* with the warm decoction of *rue* and *aromatic herbs*. A decoction of chamomile flowers, poppy heads, and rue, in the form of fomentation; and a little spirit, or oil, of anise-seed, added to the medicine, will generally give relief. A warm bath at bed-time, or the semicupium, some salt, or mustard flower, or both, having been added to the water, will also be serviceable, especially in the low or advanced states of the complaint.

287. Dr. BUTLER placed much dependence upon the *extract of conium*, in doses of one grain in the day for every year that the patient was old, in conjunction with saline aperients. It is of little service of itself; but is often an useful adjunct to the medicines already advised, especially if the child be very peevish, the abdomen pained, or the bowels irritable. Dr. CHEYNE relied most upon *colomel* with antimony at bed-time, and the common purgatives, giving the former more frequently if the complaint seemed liable to pass into hydrocephalus. Dr. CLARKE and Dr. PEMBERTON insisted chiefly on tonic infusions, after the bowels were freely evacuated. These are generally serviceable in the circumstances and combinations pointed out, and the addition to them of the extract of conium is also beneficial. In some old cases, in which there was reason to suppose that, in connection with debility, there was some degree of obstruction of the mesenteric glands, I have given the *iodide of potassium* internally, in small doses, with great advantage; but care should be taken not to prescribe it in doses large enough to irritate the stomach and bowels, otherwise it will increase the disorder.

288. *F.* The regimen and diet constitute a principal part of the treatment. Change of air, as early as possible, especially to a mild and dry air, and elevated situation, is always most serviceable. Warm clothing, frictions of the surface after the warm baths, and light but nourishing diet, are also very beneficial, particularly when convalescence has commenced. During the complaint, ass's milk, rusks, and weak broth, are suitable food. But, in the acute form, or at the commencement of the disease, even these may be

too exciting. The effect of whatever is given should be carefully watched; and the articles of diet selected accordingly. When convalescence is established, the preparations of iron, and due attention to the states of the bowels, are most necessary.

XV. HECTIC FEVER. SYN. — Ἑκτική (from ἐκτίω, constitutional, and this from ἕξις, habit of body); Febris hectica, Febris marasmodes, Febris tabida, Febris lenta, Febris amatoria, F ampherina Hectica, Atrophica, Tabes, Auct. Var.; Epanetius Hectica, Young and Good; Das schlechthendes Fieber, Hektisches Fieber, Germ.; Fièvre Hectique, Fr.; Etica Febbre, Ital.; Hectic Remittent, Decline, &c.

289. DEFIN. — Chronic, remittent, or sub-continued fever, with loss of strength and flesh, generally depending upon organic lesion or some evident or concealed source of irritation.

290. This disease is characterised by its slow and insidious approach; its prolonged duration; by emaciation and frequency of pulse; by febrile exacerbations at noon and in the evening, or after a meal, with heat in the palms of the hands and soles of the feet; and, lastly, by colligative sweats and diarrhoea. — The question, as to whether this fever is ever idiopathic, or always proceeds from some evident or concealed local irritation, has been much discussed. The greater number of systematic writers contend that it is occasionally a primary affection, or independent of local lesion. Amongst these are SAUVAGES, SAGAR, LINNÆUS, STOLL, PARR, PINEL, WILLAN, GOOD, &c.; whilst VOGEL, CULLEN, HERBERDEN, and others, entertain a different opinion. Believing that it is, in very rare cases, not assignable to any local lesion or irritation, but is owing rather to debility or exhaustion in irritable constitutions, — that, although not a primary affection, it cannot always be attributed to any local lesion, the nature and seat of which can be recognised, — I have introduced it at this place. But, whilst I admit this, I must confess that the arguments adduced by those who consider that hectic is sometimes independent of local irritation, are by no means conclusive. Dr. PERCIVAL, in his remarks, published by Dr. GOOD, states that he has seen idiopathic hectic last three months "without any pulmonary affection, and then to break out in the lungs." But the lungs may be diseased for a long time without their functions being manifestly disordered, otherwise than in causing the hectic fever, which may be thus erroneously considered idiopathic. There cannot be the least doubt that various changes may take place in parts possessed of a very low grade of sensibility and imperfect powers of preparation, as the parenchyma of several viscera, particularly the lungs, liver, kidneys, mesenteric glands, bones, &c., unattended by any pheno-

menon which will enable us to recognise their precise seat and nature, and yet give rise to hectic fever.

291. Mr. J. HUNTER contended for its idiopathic existence, by supposing that the constitution may fall into the same mode of action, without any local cause whatever, as proceeds from such cause. This is, however, no argument. He further observes, that nothing is more common than for hectic to exist in patients in whom no local disease whatever can be traced; and that, in such cases, either random suspicions are to be thrown upon the lungs, liver, kidneys, heart, or mesenteric glands, as casual symptoms may suggest, or its idiopathic nature must be inferred. Admitting that there is some truth in this, it should still be contended, that improved means of diagnosis, and a more intimate acquaintance with the origin and relations of morbid actions, have greatly abridged the number of instances in which no local lesion can be detected; and that, instead of this circumstance being common, it is remarkably rare. It is somewhat singular, that the same author, — M. BROUSSAIS, — who has written so ably against the existence of fever as an essential or idiopathic disease, should have produced, in 1803, a work on hectic fever, in which its idiopathic nature is strenuously contended for, and its various forms very minutely described — the least idiopathic of all fevers having been considered by him chiefly as such; — M. BROUSSAIS had, however, not then changed his opinions as to the nature of fever.

292. i. DESCRIPTION. — The early symptoms of hectic are — emaciation with a pale, and often fair, skin; increased frequency of pulse, especially at noon and evening, with some degree of hardness or sharpness; rapid or short respiration on any exertion; and increased heat of skin. — The exacerbations are at first very slight; but they soon become more evident, particularly in the evening; are preceded by a slight or marked chill; are attended by increased heat, which is most evident in the hands and face, the skin being at first dry; and terminate in a free, profuse perspiration, especially the evening paroxysm, which usually subsides in this manner early in the morning. The bowels are costive, but afterwards readily acted upon; ultimately they are relaxed, and colliquative diarrhoea supervenes. The urine is various, but most frequently pale and without deposit; more rarely high-coloured, and with a lateritious sediment. As the disease advances, the delicate circumscribed bloom on the cheek, which was at first only occasional, is more constant and general, especially during the exacerbations; the throat and fauces are red, dry, and irritable; the tongue is often clean, red, smooth, without papillæ, and glazed, and ultimately, with the lips and fauces, is covered by aphthous exudations; the eyes are sunk in their orbits, from the absorption of adipose matter, but are brilliant and expressive, their whites pearly and clear; the whole frame is emaciated, and the temples excavated; the hair falls out; the ankles and sometimes the legs are œdematous; sleep is unrefreshing, feverish, and disturbed; and debility with a sense of lassitude is constant, but the patient's spirits are unbroken or even sanguine. At last the diarrhoea and colliquative sweats become daily more abundant; the respiration short and precipitate; and the debility so

great, that the patient often expires when attempting to speak, or on assuming a sitting posture, &c. During the course of the disease, the sensorial functions preserve their integrity; but sometimes, towards the close, slight delirium occurs. In those cases especially which depend upon organic change in the respiratory organs, there are more or less dyspnoea, cough and expectoration; the nails become incurvated; the last joints with the extremities of the fingers fusiform, and the expectation of recovery gains strength with the progress of disease. (See TUBERCULAR CONSUMPTION.)

293. MM. BROUSSAIS, FOURNIER, VAIDY, BOISSEAU, COUTANCEAU, and some other writers, have divided hectic into three stages: the first continuing as long as the appetite and strength are not materially impaired, and the remissions are distinct; the second consisting of a small, quick, and frequent pulse, accelerated during the exacerbations, with debilitating perspirations, burning heat of the palms of the hands and soles of the feet, and rapid emaciation; the third supervening with the colliquative diarrhoea, œdema of the lower extremities, extreme emaciation and prostration of strength.

294. ii. The CAUSES of hectic fever are remarkably diversified. — It most commonly proceeds from suppuration, ulceration, chronic inflammation, excessive action, and irritation of a secreting organ or surface; from caries, necrosis, or structural change of osseous parts; and from slow inflammatory action of any part whatever of the frame. It also attends upon various adventitious and malignant productions. But in all these, it is merely a symptom of the extent to which the constitution is influenced by the local change. M. BROUSSAIS has distinguished several varieties of hectic according to the nature and seat of its principal causes; as, the *Gastric*, the *Pectoral*, the *Genital*, *Hæmorrhagic*, *Cutaneous*, *Moral*, &c. HILDENBRAND enumerates the following: the *Inflammatory*, *Putrid*, *Nervous*, *Gastric*, *Atrabilious*, *Pituitous*, *Vermineous*, *Enteromesenteric*, and *Suppurative*, to which may be added the *Puerperal*. As each of these varieties attaches to itself more or less importance, and as the division adopted by M. BROUSSAIS has been very closely followed by numerous recent writers, I shall offer a few remarks in illustration.

295. a. *Gastric Hectic* is distinguished by anorexia, thirst, dryness of the mouth, prolonged and difficult digestion, and more or less of the usual concomitants of indigestion, especially eructations, flatulence, acidity, cardialgia, &c. Sometimes the appetite is unimpaired, or is even increased, but digestion is faulty. The tongue is loaded, the mouth clammy, and the taste disordered. There are often uneasiness at the stomach, tenderness of the epigastrium, and frontal or sub-orbital cephalalgia. The complaint is exasperated by heating food, and the abuse of stimulants, which occasion a sense of heat in the stomach, or pain and cardialgia, with acid or acrid eructations. Ultimately the patient becomes pale; the breath fetid; the bowels costive, irregular, or even irritable; and the symptoms of hectic fully developed. In children, picking of the nose, mucous diarrhoea, and occasionally the expulsion of worms, are also observed; and the disorder is almost identified with, or is merely a

modification of, the remittent of children (§ 270.). This form of hectic is very probably connected, as BROUSSAIS, BOISSEAU, and others believe, with chronic irritation of the digestive mucous surface; but debility, more especially of the organic nervous system, is the primary and most important constituent of the disorder. The hectic sometimes observed to follow lactation, particularly when prolonged, is often of this kind. M. BROUSSAIS has distinguished the connection of hectic with cutaneous eruptions, by the denomination of *Cutaneous Hectic*. But the constitutional disturbance is less the effect of the affection of the skin than of the disorder of the digestive organs, with which the latter is very generally associated as a symptom.

296. *b. Pectoral Hectic* consists of the constitutional disorder consequent—1st, upon inflammation or ulceration of the larynx, and irritation of the epiglottis;—2dly, upon the various forms of bronchitis;—3dly, on the several lesions of the lungs;—and 4thly, upon chronic alterations of the pleura. It should, however, be recollected, that any of the various kinds of pectoral hectic may be associated with gastric disorder; indeed, the advanced stages of the former are always attended by more or less of the latter. Hectic arising from these lesions is fully treated of under the respective heads.

297. *c. Genital Hectic* consists of debility, associated with febrile exacerbations, caused by excessive sexual indulgences, or by masturbation; by irritation of, and mucous discharges from, the sexual passages; and, occasionally, by irritation of the urinary organs.—These phenomena not merely occasion, but also accompany and perpetuate, the hectic symptoms, until other viscera are drawn within the vortex of morbid action; the digestive organs, especially the mucous surface, or the lungs, or even both, becoming also diseased, and ultimately evincing the most prominent affection. The ill-regulated or excessive indulgences and dissipations of youth are often productive of irritation of the sexual and urinary organs, attended by more or less discharge; by debility, febrile exacerbations, and indigestion. If the indulgences which induce this disorder are continued, organic nervous power is prostrated further still; digestion and assimilation are rendered more imperfect; circulation through the lungs more irregular; and ultimately tubercular formations are developed in this organ, especially if the diathesis or other causes conspire with this in forming them.—It is an important fact, and one which is too generally overlooked, that hectic fever, induced either by irritation of the sexual organs, or by disease of the lungs, is attended by a remarkable propensity to masturbation, which counteracts but too generally every means of cure.

298. *d. Puerperal Hectic* is that form of slow fever which sometimes affects delicate females during lactation, and which, if the cause be continued, may superinduce pulmonary disease. It also sometimes follows protracted or excessive lactation, and passes either into pectoral hectic, or into a chronic state of debility, with especial disorder of some one of the abdominal viscera.

299. *e. Hæmorrhagic Hectic*, or the slow fever consequent upon loss of blood, is to be attributed rather to the pathological state giving

rise to the hæmorrhage, than to the debility caused by the loss of blood. Hectic, even in its slighter forms, seldom follows large bleedings from wounds; whilst it is a very common sequence of hæmorrhage from the pulmonary and digestive mucous surfaces; for there is generally antecedent disease, either of the mucous surfaces themselves, or of parts intimately connected with them, that sooner or later would very generally be productive of hectic fever, if no hæmorrhage had ever taken place. When hectic follows the suppression or disappearance of hæmorrhages, either occasional, habitual, or periodic, chronic inflammation or irritation of some important viscus, more especially of the lungs, the liver, the uterus, &c., should be suspected.

300. *f.* Some authors have distinguished a form of hectic from *mental or moral causes*.—There can be no doubt, when the mind becomes possessed by a predominating passion or desire, or constantly ruminates on some depressing sentiment, or continually regrets the loss of endearing objects, that the powers of life will gradually languish, and that, in delicate constitutions especially, many of the symptoms of hectic or slow fever will be produced; and, although the mental affection may not induce more than the earlier stage or slighter grade of the disease, in sound constitutions, it will frequently occasion, especially in the weak, and in those endowed with a morbid diathesis, structural change in the lungs and other susceptible organs, owing to the continued depression of organic nervous power which it causes, and to the changes resulting therefrom. Every observer must have remarked the series of changes following the loss of loved objects, disappointed or abused affections, unmerited neglect, &c.; and have recognised the influence of the mental impression upon the functions of digestion, assimilation, circulation, and respiration successively, until a predisposed organ—most frequently the lungs, the heart, or the liver—indicated a predominance of disorder and fatal tendency. In these cases, the slighter forms of hectic, the pallor, emaciation, febrile exacerbations, sleeplessness, and debility, advance slowly, and become imperceptibly associated with shortness of breath, dyspœna, short cough, hectic flushes, and morning perspirations; the lungs very frequently evincing most serious disease. In all instances of this kind, it is important to ascertain the changes more immediately consequent upon the exciting cause. In every case which I have seen sufficiently early, the vegetative or organic functions were in a debilitated or blighted state; the appetite was diminished; digestion impaired; the pulse languid, slow, and weak; the circulation through the lungs imperfect and impeded, as indicated by frequent sighing, and oppression in the thorax; and the impulse of the heart very deficient, or at times either irregular or excessive, as if this organ were labouring to overcome the congestion consequent upon the impeded circulation through the lungs. The tubercles which generally form in the course of these affections cannot be ascribed to inflammatory action, as they originate when the organic nervous power of, and circulation through, the lungs, are most impaired; but are rather a result of these latter pathological states.

301. *g.* As to the other varieties mentioned by HILDBRAND, a few remarks may be necessary.

—*a. Inflammatory Hectic* is merely that form of symptomatic fever which usually attends chronic inflammation of an internal viscus, or of a deep-seated part.—*β. Putrid hectic* is the fever sometimes attending scorbutic affections, or gangrenous and spreading ulceration, &c.; or arising from unwholesome and innutritious food.—*γ. Nervous Hectic* is the constitutional disturbance observed in persons labouring under mental afflictions, &c. (§ 300.), or chronic disorder of the nervous system, and in chlorotic and hysterical females.—*δ. Atrabilius Hectic* presents itself in persons long subject to disorder of the liver and other digestive organs—whose portal circulation has become congested or obstructed, their biliary and intestinal secretions morbid, and their digestive canal torpid or overloaded. Such persons are morally and physically depressed; are melancholic and hypochondriacal, sallow, squalid, and thin; are often affected with shortness of breath, colicky pains, disordered bowels, tenesmus, and hæmorrhoids; the stools are dark, fetid, and scybalous, and the abdomen frequently hard or tense.—*ε. Pituitous Hectic* is merely a modification of the gastric (§ 295.), attended by pituitous colivies in the prima via, owing to imperfect power of the organic nervous system. It is common in children, and is characterised by pallor, leucopneumatic indolence, and torpor; swollen lymphatic glands, increased secretion of mucus; tumid abdomen; fluor albus; the collection of viscid mucus on the tongue and teeth; coryza, mucous diarrhoea, and obscurely remitting and slight fever.—*ζ. Verminous Hectic* is a modification of the foregoing, or the association with it of worms in the intestinal canal. It is occasionally observed in delicate and relaxed, or rickety, or scrofulous, children; and in those who live in low, damp, close, and unhealthy localities and apartments, and who are subject to chronic bronchitis or winter catarrhs.—*η. The Entero-mesenteric* is a modification of the *pituitous* and *gastric*, particularly when occurring in children; or is rather the association of enlargement of the mesenteric glands with the affection of the digestive mucous surface, chiefly constituting these varieties. It is hence closely allied to the affection already described under the head of *Infantile Remittent* (§ 278.).—(See also art. *MESENTERIC DECLINE.*)

302. *h.* The varieties of hectic which arise, from the formation of matter in internal viscera, from tuberculous ulceration, from carious bones, &c., from the irritation of foreign substances, and from chronic inflammation affecting parts possessing a deficient power of reparation, present general features of resemblance, but vary in the more minute details, and differ not materially from the general description given above (§ 292.).

303. *iii.* *PROGNOSIS.*—The *duration* of hectic varies from a very few weeks to a number of years; but, however long, the tendency of the disease is fatal, unless circumstances occur or medical means be used to arrest its course—unless the causes on which it depends are removed.—The *danger* is owing entirely to these causes, and is great according to their nature.—In cases of caries, or of other local diseases which admit of removal, the fever disappears soon after the separation of the morbid from the healthy parts. When the disease depends upon the continued or repeated irritation of a secreting surface or gland,

as in its *sexual* and *puerperal* varieties (§ 297, 298.), and in the chronic forms of bronchitis and diarrhoea, it generally disappears with the cause which produced it, unless serious disease of some important viscus, as of the lungs, has been superinduced in its course. But when chronic inflammation continues to destroy, or to alter the structure of, some vital organ or deep-seated tissue, or when the substance of an internal viscus is in a state of suppuration, or when hectic proceeds from tuberculous formations, recovery seldom takes place. Yet, in some of these cases, the powers of life continue long to resist the progress of disorganisation; and occasionally at last are successful, not only in limiting it, but also in removing the chief of whatever changes had taken place. This is demonstrated in the adhesions of serous surfaces, in the absorption of purulent collections from the substance of internal viscera, or in their discharge, and in the subsequent cicatrization of the parts affected. Both the liver and lungs furnish proofs, although in rare cases, of such occurrences. Even a lobe of one of the lungs may be entirely destroyed by suppuration, and the patient recover. Where the cause is obscure, and we doubt whether the disorder is idiopathic or the consequence of some lesion that eludes detection, the patient being young, and vital power not far reduced, hopes should be entertained. But when strength is far reduced, emaciation extreme, and colliquative diarrhoea or perspiration is present, there is little or no chance of recovery.

304. *iv.* *PATHOLOGY.*—*A.* The *Lesions, post mortem*, consist—1st, of those which *caused* the fever (§ 294.);—2d, of alterations of the mucous surface of the digestive canal, upon which the diarrhoea present in the last stage mainly depended;—3d, of disease of the lymphatic and mesenteric glands;—and, 4th, of redness and inflammatory discolouration of the lining membrane of the heart and large vessels.—The various lesions from which this fever may proceed, require no further notice than has been taken of them in other articles; but those which are evidently consequent upon its early stages, which aggravate it in its course, causing the more severe symptoms characterising its latter periods, are deserving of attention.—The changes in the digestive mucous surface consist chiefly of tuberculous depositions, and of ulceration seated more especially in the lower part of the ileum and in the cæcum, with softening, and frequently with superficial redness, of the mucous membrane. The ulcers, however, are often unattended by redness, thickening, or unequivocally inflammatory appearances; and are entirely similar to those described in the article *DIGESTIVE CANAL* (§ 36, *et seq.*). The changes in the absorbent glands are the same as those described in the article *LYMPHATICS.*

305. The lesions of the circulating system have been overlooked, until notice was directed to them by BOUILLAUD, who has given the details of a number of cases of hectic, in which the internal membrane of the heart, and large vessels, both arterial and venous, presented more or less of inflammatory redness; the substance of the heart itself being often soft and flaccid, and atheromatous depositions being sometimes found in the internal membrane of the arteries.—Several years ago, I observed the internal lining of the pulmonary vein, and of its principal branches, of a

dark red and reddish brown colour, in a patient who died with tuberculous excavations in the lungs; and I have seen similar appearances subsequently in two or three cases of this disease.— But whether these appearances are the result of inflammatory irritation induced in the internal surface of the circulating system, or depend upon the action of the blood upon this surface after death, has not been satisfactorily ascertained.

306. *B. Nature, &c. of Hectic.* — Pathologists have supposed that the disease depends upon the gradual absorption of purulent, sanious, or other morbid matters into the circulation; and others have believed that it arises entirely from the local irritation — no such absorption occurring. — It is necessary to keep in recollection a few facts, which will serve to elucidate the matter. — (a) Large excavations, &c. often take place in the lungs without much cough, and with little or no expectoration, but with severe and rapid hectic absorption, in these at least, must exist to a certain extent. — (b) In such cases, the diarrhoea and night sweats are frequently very great. — (c) In caries, the hectic is also severe in proportion to the evidence of absorption. — (d) The glands in the vicinity of carious, suppurated, ulcerated, or tuberculated parts, often become affected. — (e) Irritation, excessive pain, foreign substances, &c. may long exist in deep-seated or internal parts, without inducing hectic, or causing more than the symptoms of its slighter forms or early stages, as long as these causes do not give rise to morbid secretions in the substance of the affected tissue; but, as soon as matter is collected, or a fluid is formed from the destruction of the surrounding organisation, the usual signs of confirmed hectic appear. — (f) Purulent matters have evidently formed in the liver, and occasioned hectic: the patient has recovered; and, having afterwards died of some other disease, has presented proofs, in the changes observed in this organ, that an abscess had existed in it. — (g) Lesions of the blood-vessels are not infrequent in the advanced stages of the worst forms of hectic, or those caused by tubercles and suppuration. — These facts induce me to infer — 1st, that absorption actually takes place; — 2d, that it proceeds slowly — the depurating viscera, especially the kidneys, bowels, and skin, generally removing the morbid matters, or preventing their accumulation in the blood to the extent of causing very manifest or rapid changes in it; — and, 3d, that the absorbed matters ultimately affect the blood, and not improbably the vessels also in which they circulate. I believe that the diarrhoea characterising the last stage of hectic, is caused as much by the disordered state of the blood affecting the mucous follicles and membrane, as by inflammatory irritation; and that, when this latter condition exists, it arises chiefly from the blood, and the morbid secretion poured out by these tissues. The alteration in the blood may readily be supposed to discolour, or otherwise affect, the internal surface of the vascular system, or even to inflame or disorganise it, in those vessels which proceed from the part which is the seat of caries, suppuration, or of tubercular ulceration. — As to the softening and flaccidity of the heart, upon which M. BOVILLAUD places some stress, I have seen nothing beyond what is presented by other muscular parts in these cases, the heart having partici-

parted in the emaciation or deficient nutrition of the rest of the body. — From these considerations I therefore conclude, that hectic fever is most frequently the result — 1st, of local irritation, of a slow inflammatory kind, either latent or manifest, and generally consequent upon, and associated with, debility; — and, 2dly, of the passage of morbid matters into the circulation, where they occasion most of the severe phenomena uniformly and contingently present in the last stage.

307. *V. TREATMENT.* — The means of cure must have immediate reference to the cause or pathological state on which the hectic depends. During the first and second stages, they may be often employed with success. But when the third stage has supervened, we can expect nothing from them beyond alleviating the more distressing symptoms. — a. When the disease proceeds from the association of *disease of the digestive mucous surface*, with debility (§ 295.), the treatment should consist chiefly of strict attention to diet — the farinaceous and easily digested articles of food being selected; of attention to air, gentle exercise, and to the state of the excretions; of gentle tonics conjoined with small doses of ipecacuanha and anodynes; of the infusion of cinchona with the solution of acetate of ammonia, or with small quantities of the nitrate of potash and sweet spirits of nitre, of bitters associated with laxatives, or of emollients with mild narcotics, according to the circumstances of the case. The bitter infusions may likewise be given with hydrocyanic acid, or with the extract of hop. When we suspect the existence of alterations of structure, they may be conjoined with the liquor potassæ, or with BRANDISH'S alkaline solution and conium. If the preparations of iodine be tried, very small doses only should be exhibited. A weak solution of the iodide of potassium, or of the iodide of iron, is most appropriate in such cases, either alone or with a narcotic, as hyoscyamus, conium, or extractum humuli. (See STOMACH — Diseases of.)

308. *b.* The treatment of the *pectoral and laryngeal forms* of hectic is so fully stated in the articles on the individual chronic diseases affecting the respiratory organs and passages, that nothing need be advanced on the subject at this place. It is only in the early stages of these forms of hectic especially, that material advantage can be hoped from medicine. The means just enumerated will often be found of service; but they require to be modified according to the peculiar features of the case. Gentle astringents and tonics, mineral acids, &c. are sometimes also useful. Of these, the infusion of roses with sulphate of zinc, sulphuric acid, and narcotics, is most appropriate.

309. *c.* The *sexual and puerperal forms* of hectic generally soon disappear upon the removal of their respective causes, if serious changes in remote organs have not been superinduced by a continuance of the irritating and exhausting discharges, in which the hectic originates — by the practices inducing and perpetuating the disease. In these forms the recovery depends much upon the patient himself. Early rising; mental and bodily occupations; low regimen; the avoidance of stimulating beverages, heating foods, and of warm condiments; travelling or voyaging; change of air; and a prudent regulation of the imagin-

ation; are among the most effectual means of cure. Seltzer water, soda water; the mineral waters of Pyrmont, Carlsbad, of Gielenau, of Ems, of Vichy, of Bath, of Tunbridge, &c., are severally useful, if appropriately prescribed.—When the disease is occasioned by sucking, the cure is generally speedy, if the cause is relinquished before an important organ becomes affected; and if a restorative regimen, with change of air, be adopted. In such cases, the *mistura ferri composita*, and chalybeate waters, or the mineral waters just mentioned, are very serviceable.

310. *d.* The treatment of the other varieties of hectic is not materially different from that now stated.—When the disease follows *hæmorrhages*, the means of cure should be directed especially to the pathological state of which the hæmorrhage is the result. (See that article.)—If it be connected with *cutaneous eruptions*, the state of the digestive organs, and of the frame generally, ought to claim an especial notice; and if it originate in *mental emotions*, such measures as are the best calculated to divert the mind from contemplating the sources and relations of its misery should be prescribed.—The *atrabilious*, *pituitous*, and *verminous* varieties require the combination of tonics with warm purgatives (F. 557—563. 572—576.), chalybeate mineral waters, and vegetable and mineral deobstruents.

311. *e.* When the *irritation and absorption of morbid matter* are the causes of hectic, their sources should be removed; especially when they consist of carious bones, diseased joints, puriform collections, &c. But when this indication cannot be accomplished, or when the preservation of a limb requires that every means should be tried, the treatment ought to be directed with the view—1st, of diminishing irritation; and, 2dly, of counteracting or resisting the contaminating influence of the morbid secretion on the circulation.—The first of these is to be fulfilled by a judicious use of opium, morphia, hop, henbane, hemlock, &c.;—the second, by medicines which support vital energy, and thereby resist the extension of disease, or promote the powers of reparation; as digestible nourishment, dry and pure air, gentle tonics, antiseptics, absorbents, and astringents. These may be variously conjoined, according to the peculiarities of the case—anodynes and narcotics with tonics, and tonics with antiseptics and absorbents. Thus, the infusion of cinchona may be prescribed with hydrochloric acid and the hydrochloride of morphia; the infusion of cascarrilla with the solution of the acetate of ammonia and the acetate of morphia, the tonic infusions or decoctions with the alkaline carbonates, or with the solution of potash, or with the chlorates, and the extract of hop or of hemlock, &c. Camphor may likewise be conjoined with narcotics, in cretaceous and absorbent mixtures. When vascular action becomes much excited, the nitrate of potash, or the hydrochlorate of ammonia, may be given with such of the foregoing as are chemically compatible with them; and digitalis or the potassium-tartrate of antimony may be prescribed in the more inflammatory cases, and when the bowels are not irritated.

312. *f.* Various *urgent symptoms* require to be palliated during the advanced progress of the disease. Great heat of skin will be relieved, and consequent perspiration diminished, by cold or

tepid sponging the surface with equal parts of spirits, of solution of the acetate of ammonia, and of rose water.—*Restlessness* may be diminished by the anodynes already enumerated, or by hydrocyanic acid, combined with gentle tonics and refrigerants. Camphor, henbane, and the nitrate of potash, or hydrochlorate of ammonia, are the most generally useful in this state, excepting when the bowels are relaxed, when opium, hop, or the extract of poppy should be substituted. When *diarrhæa* supervenes, the pathological conditions to which I have attributed it (§ 306.) should be kept in view, as a treatment founded upon them is the most successful in practice;—we should endeavour, in these cases especially, to counteract the contaminating influence of morbid secretions upon the circulation, and to impart tone to the digestive mucous surface. The means that are calculated to fulfil these intentions are also restorative of vital power, enabling it thereby to resist the extension of disease. The tonics and narcotics already mentioned (§ 311.) may be employed with these views; or certain of them may be conjoined with the chlorates of lime, potash, or soda; or with creasote; or with cretaceous mixtures; or these latter may be given with the compound tinctures of camphor or of opium; or with tonic and astringent extracts: or the acetate of lead, or the sulphate of copper or of zinc, may be prescribed with opium.

313. *g.* The *Diet and Regimen* are most important parts of the treatment of hectic; but they should be varied, or even different in its different states. In most cases the *food* should be digestible and moderately nourishing. The milk of asses, or milk warm from the cow, goat's milk or whey, fresh butter-milk, warm milk with one or two tea-spoonfuls of very old rum, in it; shell-fish, especially oysters; farinaceous and mucilaginous articles of diet; jellies, particularly those made with Iceland or Carrageen moss; and grapes in considerable quantity; have severally been recommended, and are more or less beneficial, according as they are appropriately prescribed. In most cases, the patient should take very gentle exercise in the open air, when it is mild, and expose himself to the sun and air as much as possible without the contingent risks. In some instances, especially those caused by debilitating discharges, by caries, &c., old wine, especially sherry, port, hermitage, and Burgundy, may be allowed with much benefit; and either old Madeira or sherry may be taken in Seltzer water. It is in such cases, especially, that the mineral waters recommended above (§ 309.) are most serviceable. (See also the articles *ABSCESS* (§ 55.), *ABSORPTION* (§ 15.), *BLOOD* (§ 143. *et seq.*), *MESENTERIC DECLINE*, *TUBERCLES*, *TUBERCULAR CONSUMPTION*, &c.)

314. DEFIN.—*The changes constituting fever proceeding in one series, frequently with a tendency to exacerbation and slight remission.*

315. i. *Of the Division of continued Fevers.*—Fevers of a continued type are so remarkably modified by the circumstances stated above (§ 43.), by varied combinations of causes, states of constitution, predisposition, and by epidemic influence, each form insensibly passing into the one nearest allied to it, that every attempt at arranging them must necessarily be more or less conventional, and depend upon characters, which, although the more prominent and universal, as respects certain species, yet occasionally disappear, or blend with others distinguishing correlative forms and varieties. Owing to this circumstance, the divisions of continued fevers adopted by writers have been arbitrary and varied. *Stoll* arranged them as *Inflammatory*, *Putrid*, *Bilious*, and *Pituitous*,—a division not materially different from that previously made by *Sydenham*, *Hoffmann*, and *Boerhaave*.—*Cullen*, *Parr*, and others distinguished three species—namely, *Synocha*, *Synochus*, and *Typhus*: *J. P. Frank*, also three—the *Inflammatory*, *Gastric*, and *Nervous*. *Richter*, four—the *Inflammatory*, *Nervous*, *Putrid*, and *Gastric*. *Borsieri*, five—the *Ephemera*, *Simple Synochus*, *Putrid Synochus*, *Slow Nervous Fever*, and *Hæctic*. *J. Frank*, four—the *Typhoid*, *Gastric* or *Bilious*, *Rheumatic* or *Catarrhal*, and the *Inflammatory*: and *Hildenbrand*, five—the *Inflammatory*, the *Septic*, *Nervous*, *Gastric*, and *Hæctic*. *Dr. Fordyce*, in his dissertations, attempted no arrangement beyond that into the *regular* and *irregular* forms. *Pinel*, desirous of giving precision to his descriptions, divided fevers of the continued type, into *Inflammatory*, *Bilious* or *Gastric*, *Mucous* or *Pituitous*, *Putrid* or *Adynamic*, and *Malignant* or *Ataxic*; and has justly considered the plague and puerperal fever as distinct from the fevers belonging to these orders. A nearly similar arrangement has been followed by *Boisseau* and *Bouillaud*. *Dr. Wilson Philip* has described only two species—*Synocha* and *Typhus*. *Dr. M. Good* three—*Inflammatory*, *Typhus*, and *Synochal Fever*. *Hufeland*, four—*Inflammatory Fever*, *Nervous Typhus*, *Putrid* or *Infectious Typhus*, and *Gastric*

Fever. *Dr. Tweedie* has divided continued fever into *Simple*, *Complicated*, and *Typhus*. *Dr. Armstrong*, into the *Common Simple*, *Common Congestive*, and *Typhus*: and *Dr. Burne*, into the *Inflammatory* and the *Adynamic*, either of which he believes may be simple, or associated with local inflammation. *Dr. Armstrong*, having recanted his former opinions respecting fever, and discarded the influence of infection in causing it, has denied the existence of a synochal or simple inflammatory fever; has considered congestive fever to pass into simple fever, or inflammation, when excitement supervenes; and has argued, that typhus always arises from malaria, is essentially the same disease, as intermittents and remittents, and differs from them only in type. The various fallacies into which he has fallen respecting the diseases under consideration, will appear more fully hereafter.

316. *Dr. Southwood Smith* has viewed continued fevers, “as one great malady never differing in nature, but in every two cases differing in intensity, and giving rise by these differences to various forms of disease”—that this difference alone is the cause of the different forms it assumes. He accordingly admits only of grades of intensity—the first or lowest grade being *Synochus mitior*; the second, *Syn. gravior*; the third, *Typhus mitior*; the fourth, *Typh. gravior*.

317. This view, as involving fundamental principles of pathology and practice, which, if implicitly followed, would lead to very serious results, requires a few remarks. *Dr. Smith's* position is that continued fever never differs in nature. Now, by the nature of a disease is understood its seat, the tissues affected by it, or the exact pathological condition, whether of vital function or of structure, constituting the malady. If, therefore, it can be shown that in the continued fevers, even of temperate climates, the state of function and organisation are always the same in kind—that the vital manifestations and structures are affected in them all in a similar manner, but in different grades of severity,—it will be conceded that fever never varies in its nature. As this position, however, is merely assumed, without any attempt at ascertaining its stability, it must still be doubted, until either it or its opposite be proved. If we closely observe the mode as well as the degree in which the vital manifestations in the nervous system, in the muscular system, in the blood and vascular system, &c. are affected, in the various forms of continued fever, and the consequent changes in the various functions and structures, we cannot fail of concluding that, however nearly they all may approximate each other, they differ as essentially in nature as in grade.—What is the difference as to intensity between the continued fevers enumerated above (§ 44.), or even between the epidemics observed at different epochs and seasons, if intensity be the only source of distinction? In the paragraph just referred to, other essential differences, arising out of the prominent affection of particular functions, tissues, and systems, are stated; and from these, as well as from the very distinct and even opposite manner in which the vital manifestations, more particularly the organic nervous power, are affected, the varieties of continued fevers result. If fevers were modified in severity merely, they would be mutually convertible into each other, and either species indifferently would rise from one and the

fame cause. But no such occurrences are observed; for the nature, as well as the intensity, of fever varies with the kind and combination of causes producing it. Will infectious typhus communicate simple continued fever, or bilious inflammatory fever, or gastric fever, or climate fever, or epidemic yellow fever; or will these species of continued fever arise from the same cause, and admit of being resolved into grades of intensity merely? No one capable of distinguishing disease ever saw the typhus miasm occasion any of these fevers, nor the causes usually giving rise to either of them produce typhus. Neither of them is convertible into the other; and however closely allied or equally severe certain varieties of each may be, something more than difference in intensity is to be recognised. The causes of each are distinct, the features of each different, the course and duration different, the external appearance and internal lesions different, and yet no difference as to severity or intensity may often be ascertained by the ablest pathologist. Is it to this assumed difference of intensity merely that we are to impute the admitted fact, that, in the very same period or stage, the treatment which is beneficial in the one fever is death in the other, — that large depletions are required at the commencement of one species, and most injurious at the same period of another? The very varied, and even opposite, treatment required in several epidemics, even when the same organs are prominently affected, cannot be referred to grades of severity; for fevers, even of this climate, may be equally violent or severe, and terminate fatally after the same duration, and yet be aggravated, or ameliorated, by opposite measures. The great pathological truth, — which ought never to be overlooked, and without a full recognition of which, in estimating the nature and treatment of fevers, our experience will be worse than useless — will be deceptive, and our knowledge worthless empiricism, — namely, that the vital manifestations vary, all or severally, be variously affected by the causes productive of fever — may be lowered or heightened, or otherwise changed; and that these changes, whether as to kind or as to degree, should be made the basis of distinction, in arranging the varieties and forms of fever, and in devising indications for their cure. In the following inquiry, something more than intensity of action will be recognised and made the grounds of arrangement and treatment, inasmuch as each of the several kinds of fever presents characters having stricter reference to the nature, than to the grade, of disorder — to the state of vital manifestation in the several systems and structures, and to the seat and grouping of the predominant lesions, much more than to intensity of morbid affection. The arrangement, therefore, about to be followed, will not materially differ from the sketch already given (§ 44.). But all the kinds of fever there enumerated cannot be treated of under this head; their importance, and, still more, certain peculiarities of character, as well as of the circumstances in which they occur, requiring, conformably with the form of this work, that they should be discussed in separate articles. In considering, therefore, the various kinds of continued fever, those only which are most intimately related to each other will be comprised under this head; the more simple states

being first described, and the more complicated and dangerous forms successively reviewed.

318. ii. *Of the Prognostic Symptoms in Continued Fevers.* — *a. The countenance.* — When the expression is serene, confident, clear, and animated, the disease is of a mild and uncomplicated kind; in the advanced stages this state indicates a favourable crisis. If the face is large, injected of a crimson or dark colour, with prominence of the eyes, or is agitated and anxious in the early stages of fever, the morbid excitement and determination to the head occasioning this appearance will speedily exhaust the powers of life, and, in a later period, will soon be followed by malignant symptoms, or fatal collapse. When the countenance is tinged of a yellowish or earthy hue, or is withered-like or sunk, or constricted, and especially if it exhibit distress, or want of serenity and confidence, extreme danger may be apprehended. A full, bloated, waxy, or livid countenance, particularly if it assume a tawny or mahogany tinge, indicates very dangerous congestion and approaching death.

319. *b. External surface.* — If the skin be soft and perfect in its sensibility, its heat not excessive, although augmented, but without a feeling of pungency or burning; and if its temperature be equally diffused; a mild attack may be expected. But when the skin is dry and harsh, as if thickened, and the heat is ardent, caustic, or unnatural; if the surface be little sensible, not readily acted upon by rubefacients or blisters; or if vesicated parts assume a dark or black hue; if the heat be ardent in the head or trunk, particularly at the epigastrium, and lowered in the extremities; if the skin be thickened, apparently withered, dusky, dark, or livid in parts, or yellowish, flaccid, tawny, streaked of different shades, lurid, or otherwise changed from its natural hue; if it be damp, greasy, puffy, or bloated, or studded with very dark petechiæ, vibices, or blotches, or unusual eruptions; or if parts pressed upon show any tendency to gangrene; great depression of the vital powers, with contamination of the circulating fluids, should be inferred, and the danger considered great. The more florid, however, the spots are, the less is to be feared; and when the black or violet petechiæ assume a brighter tint, a more favourable opinion may be formed. Large black or livid spots are often attended by dangerous hæmorrhage from the bowels. Small dusky brown spots, like freckles, are very unfavourable signs. Large livid or dark greenish marks seldom appear till very near the fatal period. (ПУХЛЯК.) — If the skin be covered by warm, general, fluid and copious perspiration, attended by an open or free pulse, a favourable issue may be expected. But, if the perspiration be cold, clammy, scanty, or partial, with a nauseous or disagreeable odour, especially if the pulse be weak, small, very frequent, oppressed, or irregular, there is much danger. The occurrence of erysipelatous or erythematic inflammation in the seat of sores or of abrasions; the breaking out of old ulcers, or the opening of cicatrices; or a foul, gangrenous state of old sores; denote sinking of the powers of life, and a tendency to a dissolution of the textures. — *Emaciation*, when moderate, and in due relation to the duration of the disease, is rather favourable; but, when it is excessive or rapid, it indicates ulceration in the

bowels. Little or no wasting, or a bloated and a soft or tumid state of the surface, is very unfavourable, and, with discolouration, indicates a malignant malady. — The supine position; inability to turn or remain upon the side; falling down in the bed; or the head being buried deep in the pillow, from frequently throwing it back, or rolling it about; are indications of great danger.

320. *c.* The *abdomen* should be carefully examined, in order to form an idea of the probable state of the stomach, liver, spleen, and bowels. — Tension, oppression, and pain in the hypochondria and epigastrium, indicate predominant affection of the liver, stomach, or spleen; and, if to these be superadded sickness and vomiting, or a sense of internal heat or burning, tumefaction or tenderness, a harsh or caustic heat of the surface of these regions, with a parched skin, great thirst, dark-coated tongue, or great anxiety at the præcordia, a very severe form of fever, which will probably pass rapidly into exhaustion, with various malignant symptoms, should be anticipated. — A tympanitic or distended abdomen; soreness, tension, intolerance of pressure; or a sense of heat or burning; with a hot, dry, harsh, and dusky skin; or with watery, foul, and morbid alvine discharges; or with a dark-coloured tongue; are most unfavourable signs. If any of these be accompanied with irregular or irritable bowels, and the state of the discharges just mentioned, or with mucous or bloody stools, asthenic inflammation, frequently with ulceration, or some equally dangerous lesion of the intestines, is present. If, at an advanced period, or after any of these symptoms particularly indicating disorder of the bowels, very acute pain suddenly occurs in the abdomen, extending from a circumscribed spot, with vomiting, collapse of the features, increased frequency and smallness of the pulse, abdominal distension, tenderness, &c., perforation of the intestines, and its consequences, have taken place.

321. *d.* *Anxiety* at the epigastrium and præcordia, with intolerance of pressure, depends upon the affection of the nerves of organic life, and serious lesion of the stomach and heart, and accompanies the worst forms of fever. — When attended by great restlessness, it is a most unfavourable sign. It often ushers in, and accompanies, dark, grumous vomiting in malignant and disorganising fevers. — *Singultus* is also often consequent upon this sensation, especially when the stomach, or superior and posterior parts of the liver, or both organs, are much affected. When it appears late in the disease, and has been preceded by pain, or by a sensation of heat or burning at the epigastrium, or by distension, oppression, and tumefaction in the hypochondria, dissolution is generally impending, particularly if the singultus be obscure or suppressed, and attended by anxiety or tension at the præcordia.

322. *e.* *Sensibility and excitability* vary much in different forms and stages of fever. — During moderate excitement, or reaction, when there is no disorganising tendency in any viscus, these manifestations of life are increased and equally diffused. But when the disease evinces at its commencement, or at an advanced stage, depression of the vital powers, with signs of contamination of the fluids, and tendency to a solution of the vital tone or cohesion of the tissues, the excitability or irritability is evidently diminished, either by the

exciting causes, or by previously increased action, or by both; and, in such cases, it is often unequally manifested, or concentrated in those viscera which are most severely affected. Morbidly increased sensibility and excitability, especially when so great as to give rise to spasms or convulsions, or augmented activity of all the senses, and of cutaneous sensation, are indications of affection of the membranes and surface of the brain and spinal chord, with a tendency to exhaustion, great in proportion to the degree of sensibility displayed. — In many of the forms of fever characterised by severe cerebral affection, followed by stupor, black tongue, low delirium, or coma, the vital manifestations under consideration are suppressed by the cerebral congestion, as well as unequally diffused or manifested. In all such instances the prognosis should be very unfavourable. But, when these vital states seem neither suppressed nor much lowered, nor very inordinately excited, nor unequally manifested, the surface of the body, the senses and nervous system generally, still retaining their susceptibility of external and internal impressions, a favourable issue may be expected. When the extremities are cold or clammy; the skin thick, dry, loose, or hide-like; the countenance sallow or collapsed, with increased or caustic heat at the epigastrium; we may infer the excitability to be unequally manifested; to be diminished in the periphery of the body and augmented in the more central parts, particularly if irritability of the stomach and bowels, with morbid discharges, be also present.

323. *f.* The *cerebral functions* are more or less disturbed in most continued fevers, and require, as well as the state of the senses, the close observation of the physician. — If the *sleep* be sound, undisturbed by frightful dreams or sudden startings unattended by stertor, or moaning, and especially if the patient awakens in a more rational or refreshed state, a favourable issue is indicated. But in proportion as the sleep deviates from this, are severity of disease and danger to be apprehended. An agitated, unrefreshing sleep indicates increased vascular action in the brain; and this is still more to be dreaded, if there be continued watching. Want of sleep often precedes delirium in its worst forms. Stupor, or a desire to sleep, without obtaining it, indicates great danger. — Violent and furious *delirium*, or early delirium, with great excitement of the circulation, irritable or rapid pulse, crimson-coloured and injected countenance, prominent eyes, and rending headache, indicate a state of vascular excitement, which will soon be productive of dangerous exhaustion, even if the brain escape immediate or irremediable mischief. — If delirium be attended by convulsions, startings of the tendons, or tremors, the danger is great, and often near. It is not less certain, although somewhat delayed, if followed by profound coma, relaxation of the sphincters, unconscious or involuntary discharges, &c. A mild delirium is not unfavourable when unattended by signs of malignancy, or extreme exhaustion of the powers of life; and if it appear in the advanced course of the disease, and chiefly in the evening. When it follows a state of stupor, it is often indicative of recovery. Very lively or very low delirium, the latter especially, is unfavourable. If the delirious patient states himself to be dying, he is generally right, although there may not be many signs of

danger present. Indifference to death, with an apparent desire of it, and a firm persuasion of being perfectly well, are also unfavourable.

324. *g.* If the *eyes* be calm, or slightly animated, in the early stages, a mild form of fever may be expected, — at advanced periods, a favourable change has commenced. Agitated, wild, terrified, confused, muddy, painful, prominent, turgid, or suffused eyes, indicate a most severe disease, at an early stage, and great danger in advanced periods, especially if the whites of the eyes become of a dusky or dirty yellow. Intolerance of light attends cerebral excitement; and rolling of the eyes, with a wild, unfixed stare, often precedes severe delirium or convulsions. A dull, sluggish state of the eyes, want of animation, sinking in their sockets, a dark hue of the conjunctiva, with a sad expression, are unfavourable. A pearly whiteness, with agitation and prominence, is a symptom of dangerous congestion of the lungs and liver; and, if succeeded by a dirty yellow hue, or dulness of the cornea, indicates approaching dissolution. Partial paralysis of the retina, indicated by black spots, or other dark objects floating before the eyes; closure or falling of the upper eyelid, or dosing with the eyelids half closed; are dangerous symptoms. — Slight *deafness* without pain in the ears, is not an unfavourable sign.

325. *h.* The *tongue and mouth* furnish important indications in fevers. — In the course of the milder forms the tongue is foul, coated with a yellowish or cream-coloured mucus, and generally furred; it is sometimes a little red at the sides and apex, and rather dry, or moderately moist, in the centre. In proportion as it departs from these states, the danger is increased. If it be covered by a milky, whitish, or mealy coating, and if it be also large, flabby, or swollen, early in fever, an adynamic or malignant state of disease may be expected. If it become rough, dark-coloured, with prominent papillæ, and not particularly coated, but dark red, especially towards the sides, serious affection of the alimentary canal, or of the liver, should be feared; more especially if the symptoms referrible to the abdomen and these viscera be also urgent. If to these appearances be super-added dryness, and contraction of its breadth, serious or fatal changes within the head, or large cavities, have supervened. When the tongue is white, or coated with the papillæ, erect or excited, and the edges red and fiery, vascular action is then inordinate in some internal organ, although no other symptom may indicate this state; and vascular depletions are required. If it be covered by a deep yellow coating, congestions of bile in the biliary ducts and gall bladder are evinced; and if this pass quickly into an excited, dry, and brownish state, the supervention of congestion, or inflammatory action in the substance of the liver, or the digestive mucous surface, or in both, with diminished vital power, may be inferred. A dark or brick-coloured, or livid redness of the tongue, with a glossy surface, or a surface partially covered by a partly detached coating, or black crust, or with a dark, scanty, tenacious rancus in the mouth, or on the teeth or lips, show extreme prostration of vital power, with contamination of the circulating and secreted fluids. A leaden-coloured, sodden, or parboiled-like, flaccid, smooth, enlarged, tremulous, or dimi-

nished or shrunk, tongue, are all unfavourable signs. If this organ become, in the progress of fever, thickly covered by a dark or fuliginous coating, or exhibit, in addition, deep fissures, the apex and sides being of a brownish or dark hue, the adynamic state is extreme, and the digestive mucous surface will readily pass into ulceration or sphacelation, if, indeed, the former lesion have not already commenced. — Vital exhaustion, contamination of the fluids, and solution of the soft solids — the constituents of marked malignancy — are evidently present, if the gums readily bleed when touched, if they and the teeth are covered with a black viscid mucus; if the former discharge a dark dissolved blood, or ichorous bloody sanies; or if a similar fluid escape from the nostrils or posterior fauces. An inky state of the surface of the tongue sometimes ushers in these symptoms, and also evinces the malignant condition. On the other hand, if the tongue becomes cleaner at its edges or apex, or moister round the margin, particularly if other favourable signs appear, a salutary change has commenced.

326. *i.* *Thirst* is often very urgent, or even insatiable; but, although indicating the intensity of disease, it is not of itself a dangerous symptom. — The absence of thirst, especially when the tongue and fauces are dry, rough, and parched, is always an unfavourable sign. A constant desire of drink, yet the patient drinking little when it is given him, and a difficulty of deglutition, are very dangerous symptoms.

327. *k.* The *evacuations from the bowels* furnish important signs to guide the practitioner in the treatment and prognosis. — In the milder forms of fever the bowels are readily acted upon, and the evacuations are generally feculent, but varying in colour and consistence, according to the state of the biliary and other secretions, and the purgatives employed. When the stools give relief from uneasiness in the abdomen, or reduce fulness of it, a mild disease may be expected. If the most active cathartics are required to produce evacuation, the stools being watery, scanty, or otherwise morbid, and voided with a sense of confinement or difficulty, the abdomen being full or tense, or hot and uneasy, a severe fever may be anticipated, and general or local depletions, or both, are indicated. If copious feculent stools follow this state, a favourable crisis may be looked for. Frequent, scanty, bilious evacuations, presenting every variety of colour, from a light green, or greenish yellow, to a greenish black, sometimes watery, at other times mucous and streaked with blood, occasionally feculent and extremely offensive, often accompany the worse forms of bilious or autumnal fevers, and indicate danger, particularly if they assume a pitey appearance. When the stools are smooth, dark brown, or blackish, like treacle, the danger is great. When they are intimately mixed with blood, or bloody sanies, or purulent mucus, or are ochrey, very frequent and exhausting, organic changes in the mucous surface of the intestines, or in the liver, are evinced. If discharges of blood are found in the stools, especially if unmixed with other matters, ulceration in the large bowels may be inferred. If the blood be grumous, black, and mixed with the fecal matters, it has generally proceeded from

the small intestines. If the stools consist chiefly of a light yellow or serous fluid, or are passed involuntarily or unconsciously, great danger may be apprehended.

328. *l.* The *urine* is always more scanty in fevers than in health, excepting during the premonitory and invading periods, when it is often pale and copious. As reaction is developed, it is diminished, and higher coloured than natural. In proportion to the extent of these latter changes, may the disease be considered as severe.—In the most dangerous forms of fever, particularly those characterised by morbidly increased action, rapidly passing into the malignant or adynamic states, the urine is extremely scanty, and its secretion nearly suspended. If it also present a muddy, or greenish brown, or greenish black hue, great danger exists. A greenish or dark urine is often observed in severe inflammatory, bilious, and gastric fevers, sometimes with a muddy appearance, or with darker clouds in it. When this kind of urine becomes paler, deposits a sediment, especially if it assume a brick colour, and is abundant, a favourable change is taking place. If this secretion become more copious and more natural, with a due deposit, the fever is declining. But if it be more scanty, or suppressed, or passed involuntarily, or if retention occur, extreme danger exists.

329. *m.* The *respiration* is generally frequent or irregular in all severe forms of fever. When it is also attended by a sense of constriction or oppression, or when it becomes short, hurried, difficult, and laborious, or suspirious, great danger is evinced. A still, quiet respiration, the motions of the thorax being scarcely perceptible, is also unfavourable, especially when stupor or torpor is present. A slower state of respiration than natural, occasionally interrupted by deep sighs, or by convulsive heavings of the chest, is a sign of danger. A very hot state of the expired air early in the attack indicates an inflammatory or malignant fever. A coldness or rawness of the expired air, particularly if it have a fishy or otherwise offensive odour, indicates either a malignant disease or approaching dissolution. In all cases of disordered respiration, especially if cough be present, the stethoscope should be used, unless there be any dread of infection.

330. *n.* The *pulse*, to the experienced and observing physician, furnishes the chief indications of danger, as well as of treatment. If it be under 100 or 110, at the same time free, energetic, and regular, the disease will be mild and tractable. But if it rise above the latter number, if it become also irregular, tumultuous, or oppressed, then danger is to be dreaded. If it reach 120, and especially if it rise above this number, the danger is very great. If it mount to 130, recovery seldom or never occurs, unless in cases of hysterical and irritable females, or those in the puerperal state. Smallness, weakness, irregularity, intermissions, or startings of the pulse; or a too open, broad, and very soft pulse, the pulsation ceasing upon slight pressure of the finger; are all indications of great danger. If it become less frequent, more free and expanded, a favourable change may be hoped for. An intermission every fifth or sixth beat, at the acme of the disease, is sometimes an indication of crisis.

331. *o.* The *blood* taken from a vein furnishes

very important indications, both as to the means of cure and as to the result.—If it be not materially different from natural, or if the crassamentum be merely slightly cupped, a favourable opinion may be formed. But if the clot be loose, gelatinous, or imperfectly separated from the serum; or if it be dissolved or broken, and tinge the serum; or if the serum be of a brownish or greenish hue; or if the more remarkable changes mentioned in the article *BLOOD* (§ 129. *et seq.*) be present; most dangerous disease obviously exists, depending no less upon the alteration of this fluid than upon depression of the vital manifestations with which this alteration is associated, and of which it is usually the consequence.

332. *p.* The prognosis, moreover, depends very much upon the *form of the fever*: at least one third of the more malignant kinds of fever terminating fatally, according to the usual modes of treating them, and not more than one case in fifteen or twenty of the milder forms.—The *nature of the prevailing epidemic* must be taken into account, in connection with the *circumstances* that seem to favour or extend it. Of these the most remarkable are full living, and a plethoric state of system. Although the epidemic fevers, lately prevalent in Ireland, have been produced by the wretched circumstances of most of the lower classes, and have readily spread, owing to these and other allied causes, the mortality has not been generally great in these classes, in proportion to the number affected; whereas, amongst the higher orders, the extension of fever has been relatively less, but the proportion of deaths to the affected much greater, than in the lower. Persons who live chiefly on animal food, or who partake of it very largely, are in greater danger from continued fever than those who live abstemiously, or chiefly on vegetable diet.

333. *q.* The *age and strength of the patient* should also be taken into the calculation.—Early age and strength do not furnish the protection from fever, nor yet from an unfavourable termination, that is very generally supposed. Indeed, in some malignant fevers, the young and strong are placed in the greatest jeopardy; as in epidemic yellow fever and plague. The continued fevers of this climate are most prevalent from the fifteenth to the thirtieth years. The proportion attacked during this period may be reckoned, as to all the other periods of life, as three are to two; whilst the number of deaths in the former, compared with the latter, may be considered as ten to nine; showing that, although the predisposition to fever is greatest at this particular period, the danger is less. After forty years, the risk rapidly increases with the progress of age.

334. *r.* *Sex* has some influence as to the prognosis of fevers even in this country. But, in warmer and more unwholesome climates, and in certain epidemics, it should have considerable weight.—In fevers proceeding from infection, marsh exhalations, and suppressed perspiration, and in various epidemics, a larger proportion of males is generally attacked, owing chiefly to the circumstance of their being exposed more than females to those causes. The latter are, also, upon the whole, less severely affected, owing—1st, to their much less exposure, and the consequently less intense action of the causes;—2dly, to the less rigidity of their fibres;—and 3dly, to the periodic discharges

to which they are subject: hence deaths amongst females attacked are less frequent.

XVII. FEVER, ARDENT; *Febris Ardens*.—CHARACT.

— *The stages or series of febrile phenomena proceeding with rapidity and regularity; the period of excitement being very acute, and attended by greatly increased vascular action; no morbid seminum or infectious miasm being generated in their course, as observed in modern times.*

336. Under the generic denomination of *Ardent Fever* may be comprised those more acute forms of fever which are attended by great vascular excitement, and which, owing to their nature and severity, generally run their course in from one to fourteen days, and are but seldom prolonged beyond nine or eleven days. They may be divided into the more ephemeral and the inflammatory.

i. EPHEMERAL FEVER. SYN.— *Diary Fever, Febricula, Ephemera, Febris diaria*, Auc. Var.; *Simple Fever*, FORDYCE; *Das eintägige Fieber*, Germ.; *Fièvre éphémère*, Fr.; *Effimero*, Ital.; *Efemera*, Span.

337. CHARACT.— *Increased frequency and strength of pulse; with heat of skin, headache, thirst, and white excited tongue; terminating in perspiration generally within twenty-four hours.*

338. *Simple Ephemeral Fever* may occur in a very mild and slight form,—the *Ephemera mitis* of Dr. GOOD; or in a much more acute state,—the *E. acuta* of this writer. But intermediate grades between these may also present themselves.

339. *A. Causes*.—The *mildest variety* is usually caused by excessive or prolonged muscular exertions; by the more violent passions and emotions of the mind; by protracted study and mental occupations or excitements; by vicissitudes of temperature, and exposure to a warm sun; and by disorder of the digestive organs, proceeding generally from the quantity and nature of the ingesta.—The *more acute states* usually arise from the above causes, from a surfeit, from temporary obstruction or congestion of the biliary organs, from the presence of faecal collections and morbid excretions in the prima via, and from violent exercise under a hot sun.

340. *B. Symptoms*.—*a.* The *milder form* of ephemeral fever is rarely preceded by chilliness or rigors; but it generally commences with lassitude, yawning, stretchings, and a sense of irritation or of undue excitement. The pulse becomes frequent, the skin hot, and the head pained. The patient tosses in bed—is restless; cannot sleep, or sleeps in a very disturbed and interrupted manner; and his tongue and mouth are dry. These symptoms frequently commence in the afternoon or evening, and subside in the course of the succeeding morning, in a gentle perspiration; thus terminating in from eight to fourteen hours. But often, also, when the cause has been more severe, and the disorder has come on at a later hour, the patient continues feverish in the morning after a restless night; is indisposed to leave his bed; feels unrefreshed, and unable to make any exertion; and passes the day in disquiet. Towards evening, the restlessness and other febrile symptoms increase; but in the night, or at an early hour in the morning, he falls into a quiet sleep; a perspiration breaks out; and he awakens refreshed and restored.

341. *b.* The *more acute form* often begins—especially when it is caused by disorder of the digestive organs, or by cold—with chilliness or rigors, succeeded by great heat of skin and throbbing pain of the head. The pulse is frequent, strong, and full; the face is flushed; the urine high-coloured; the tongue is white, the papillæ erect; and the secretions and excretions are diminished. These, and the usually attendant symptoms—as restlessness, languor, want of sleep, and general uneasiness—having continued from twelve to twenty-four hours, a free perspiration supervenes, generally towards morning; the urine deposits a sediment, and the disorder disappears. When this form of fever proceeds from mental emotions or excitement, and from exposure to a hot sun, or from muscular exertions in warm weather, or from a rapid transition to a hot climate, it is seldom or never preceded by chills or rigors, and, if not actively treated by antiphlogistic remedies, is often prolonged beyond the period just mentioned, and assumes all the characters of the next species—*Inflammatory Fever*.

342. *C. Diagnosis*.—These states of disorder may be mistaken for the commencement of some one of the more serious forms of fever. But they may readily be distinguished by ascertaining their causes; by the absence of the usual premonitory signs of fever; by the sthenic and acute vascular excitement, nervous energy being very little impaired; by the rapid increase of the heart's action, by the slight depression of the muscular powers; and by the circumstance of pain being either hardly complained of in the loins and limbs, or altogether absent.

343. *D. Treatment*.—The febrile symptoms soon subside after the digestive canal is freely evacuated, especially when they have arisen from the irritation produced by retained excretions. When they are caused by the ingesta, an *emetic* should be given immediately, and its operation promoted by the usual means; but it is contra-indicated in all other cases. Afterwards a dose of calomel ought to be administered, and allowed to act upon the secretions for five or six hours. Cooling *saline purgatives*, conjoined with small doses of antimony, or of ipecacuanha, as advised by VATER and GIANELLA, or of the spirits of MINDERER, repeated at short intervals, will then hasten recovery, and remove the morbid secretions which have disposed the frame to these febrile attacks.—When the disorder has been occasioned chiefly by atmospheric vicissitudes, *diaphoretics*, especially after the bowels have been freely evacuated, and a tepid or warm bath, are more particularly indicated.

344. If the febrile attack have been caused by inordinate mental excitement and exertion, or by fits of passion, by anxiety or other affections of mind, *cold* should be applied to the head, in the form either of affusion, of cold water, cold sponging, evaporating lotions, &c.; the bowels freely evacuated, and diaphoretics prescribed.—If it be produced by exposure to, or by muscular exertions under, a hot sun, and whenever vascular action is excessive, or the patient plethoric, *full bloodletting* ought to be practised previously to the last specified means, which should be assiduously employed, and accompanied by cold sponging of the surface, and the internal use of refrigerants and saline medi-

cines. The febrile attacks which follow exposure to the sun in warm climates, or even the quick transition from a cold or temperate to a hot country, when treated thus actively at their commencement, generally subside within twenty-four hours. But it is comparatively rare that a seasoning or climate fever runs its course in so short a time, unless in delicate or thin persons, and when the attack is very slight. In these cases, particularly when the stomach is irritable, much benefit will accrue from the frequent exhibition of small doses of the nitrate of potash, or of it and the muriate of ammonia, in solution, as prescribed by HILLARY, nearly as follows:—

No. 221. Potassæ Nitratis gr. xx.; Ammonia Hydrochloratis gr. xij.; Mist. Camphoræ ʒij.; Aquæ ʒx. M. fiat haustus, quartis vel sextis horis sumendus.

345. DEFIN.—Pain in the head, back, and limbs; heat generally and greatly increased; pulse full, hard, and accelerated; thirst urgent; urine in small quantity and high coloured; the bowels constipated, with restlessness and anxiety.

346. A. FORMS.—a. MILD INFLAMMATORY FEVER.—α. The fever which usually arises from cold and dry states of the air, in cold climates, in elevated situations, or in temperate countries, from atmospheric vicissitudes or other causes, assumes either simple or complicated forms, and is generally sporadic. Its epidemic occurrence is comparatively rare, especially in its simple state. It appears chiefly during winter and spring, or during north and north-east winds. In its complicated states, which are most frequent, it forms a connecting link between idiopathic fever, and visceral inflammation; the local affection appearing in the early or advanced course of the former, the general disorder, or symptomatic fever, being consequent upon the latter. Thus

inflammatory fever, and local inflammation, arise most frequently from the same causes acting upon different constitutions, habits of body, and states of local or general predisposition;—the simple form of inflammatory fever appearing in the young, plethoric, and robust, and in those possessed of no local predisposition; the complicated form taking place in persons whose previous ailments, habits of life, or avocations, have induced a disposition to predominant action in some important viscus, or from a concurrence or succession of external causes tending to the more especial disorder of one or more organs; and the primary local inflammation occurring from a predisposition of some part so great as to experience the onus of morbid action from the commencement, or soon after the impression of the exciting causes, or from the kind and concurrence of these causes.—In the first case, the whole frame seems to participate equally in the disordered action from the beginning: in the second, the disorder is also general from the first, with predominance of it evinced in some organ, either at a very early period, or in some advanced stage: in the third, the earliest symptoms of disease are referred to a particular viscus, and with the increase of such disease the whole system sympathises.

347. β. The symptoms of this variety are uniform in kind, but vary in severity. The premonitory signs are usually slight, or of brief duration. Hence the attack seems sudden, and is commonly ushered in with rigors or chills which are of short continuance; and, although often well marked, are occasionally so slight as to escape observation or recollection. The rigors or chills seldom recur, and are rapidly followed by general vascular reaction: the skin and integuments become full, injected, dry, hot, and burning; the countenance full, glowing or red, and animated; the eyes injected, intolerant of light, but lively; the pulse frequent, strong, bounding, and full, sometimes hard or oppressed; respiration is frequent, and the expired air hot; the nostrils and mouth are dry; the tongue white, its papillæ excited or erect; and the lips full and red. The external appearance of the body evinces increased vital action; the whole surface appears glowing and animated; the internal sensations indicate generally increased vascular activity; and all the secretions and excretions are diminished or obstructed. The patient complains of great thirst and heat; of a severe or throbbing headache and vertigo; of anxiety at the præcordia; of increased sensibility, especially in respect of light and noise; of restlessness, watchfulness, and of frightful dreams; and of nausea or sickness. Taste and smell, owing to imperfect secretion on the surface of the organs, are impaired or abolished. The pulse seldom reaches 110 beats in a minute; and the heat of skin, although greatly increased, is in due relation with the activity of the circulation; and does not impart the harsh and unpleasant sensation to the hand of the observer, that characterises the more unfavourable kinds of fever. Upon issuing from the vessel, the blood is usually red or florid, viscid, and thick; and separates perfectly into serum and coagululum: the former of which is limpid, watery, and in small quantity; the latter firm and sometimes cupped, but it seldom exhibits the

buffy coat unless local inflammation have supervened.

348. The symptoms commonly increase in severity: the tongue becomes red and dry; the urine more scanty, and of a higher colour; the bowels more constipated, and the watchfulness more prolonged. In children, heaviness, drowsiness, or *šopor*, is frequently observed; and in adults, delirium or reverie sometimes occurs. All the phenomena usually are exasperated in the evening; their mitigation in the morning being attended by partial perspiration, or a relaxed, moist, and warm state of the surface. On the third or fifth day they reach their acme. At this period they often appear somewhat mitigated; but generally continue from two to four days longer, with manifest efforts at a critical change, which usually takes place about the seventh or ninth day, and rarely later than the fourteenth. The crises commonly observed are—*hæmorrhages* from the nostrils or from the *hæmorrhoidal* vessels, more rarely from the uterus; a copious and general perspiration; and a free secretion of urine, depositing a sediment. After the natural evolution of one or more of these evacuations, the symptoms rapidly subside, and convalescence speedily advances.

349. Although the epidemic occurrence of this form of fever is rare, instances have been recorded by INGRASSIAS, HOYER, HEISTER, VAN SWIETEN, and NAVIÈRES. In these, the symptoms and progress of disease coincided entirely with the description just given.—Bloodletting, and the rest of the antiphlogistic regimen, were adopted in these epidemics, and recovery took place in nearly all the cases.

350. γ . This fever may be said to be *endemic* in warm countries, during dry seasons, especially amongst Europeans who have recently removed to, or who reside in, these countries. But in them it frequently either assumes a severer form than that now described; or, after an imperfect effort at crisis, subsides into a state of dangerous collapse. *Relapses*, also, from errors in diet; or from intemperance and premature exposure, are much more common in them, than in persons residing in northern and temperate climates, generally owing to the concurrence of malaria in producing the fever, which, however, more usually assumes the form noticed hereafter (§ 354. *et seq.*)—Mild inflammatory fever is seldom protracted beyond seven days, unless it assume an unfavourable and complicated form. The continued fever, which occurs during the hot and dry season, in the more southern parts of Europe, in the East and West Indies, and in other places within or near the tropics, particularly among the natives of cold and temperate countries who have recently removed thither, is generally either of this kind, or of the complicated or severe forms about to be described. The modifications it presents in different climates, result chiefly from the difference in the constitution and habit of the affected, from the intensity and concurrence of the causes, and from the association of malaria with high grades of temperature, and the other circumstances already insisted on.

351. δ . *The complicated states of inflammatory fever* are more common than the more simple form, whether observed in warm, or in temperate and cold, regions. They depend chiefly—(a) on

the season and climate;—(b) on the habits and occupation of those affected;—(c) on the concurrence and succession of the remote causes;—and, (d) on the previous state of particular organs.—They generally appear sporadically; occasionally they may be said to be epidemic; and in some places they are endemic.—Their epidemic appearance is chiefly in temperate countries during dry and hot seasons, and to a limited extent. Their endemic prevalence is observed under the circumstances assigned above (§ 350.). The complications may be either almost coëtaneous with the development of the fever, or consequent upon it, at any period of its course. They may be either so slight as to constitute merely an exalted affection of a certain organ, or a determination to particular parts; or so severe as to amount to a state of sthenic inflammation, rapidly passing into disorganisation.

352. (a) *The complication with predominant action or inflammation in the brain or its membranes*, occurs principally in very hot climates, in soldiers and sailors who have been exposed to a powerful sun, and been required to make considerable bodily exertion when thus exposed; in persons who have been intemperate, or have felt the exciting passions of the mind; and in those who have over-exerted their intellectual powers. In these, the fever is often very sudden in its attack; and the symptoms referrible to the head indicate every grade of affection, from active determination of the circulation to this part, to fully developed inflammation. In many of such cases it is difficult to determine whether the local or the general affection is the primary one, so early has been their co-existence. In these, the patient sometimes falls down from the suddenness and severity of the affection, with a red or tumid countenance, injected or suffused eyes, and hot scalp, but without loss of consciousness. In others, predominant disorder in the head appears only in the advanced progress of the fever; the patient complaining of severe throbbing and distracting headache, and of a feeling as if the cranium would burst from internal distension. In either case, violent delirium, or maniacal excitement, often supervenes, and rapidly passes into coma, or stupor, or is removed by treatment. In all, the secretions and excretions are impaired, and the bowels constipated.

353. (b) *Predominant affection of the lungs, or pleura*, forming the pulmonic complication, is observed chiefly in cold or temperate climates during dry and cold seasons, and high winds; and in elevated situations. In intertropical countries it occurs only in the cooler seasons, and in elevated localities. Sudden vicissitudes of temperature, damp clothes, and exposure to the night air, after experiencing heat and fatigue, are the most common exciting causes.—The affection of the lungs is frequently either not fully developed, or is latent at the commencement of the fever, and is, consequently, often overlooked after it is established, unless it extend to the bronchi on the one hand, or to the pleura on the other; and then the symptoms characteristic of either will direct attention to the complication. The stethoscope should therefore be employed whenever the breathing is laboured or oppressed in the inflammatory states of fever observed in the circumstances just stated.—This fever may present also

prominent *Hepatic, Gastric, and Enteric disease*; but, in such cases, it will very nearly resemble the forms of fever described under the names *gastro-bilious and mucous*.

354. *b. SEVERE INFLAMMATORY FEVER.*—The disease described by the names of *Synochus Causonides*, by GILBERT; of *Synocha Causodes*, by MANGET; of *Synocha Ardens*, by SAUVAGES; of *Endemial Causus*, by MOSELEY; of *Inflammatory Endemic*, by DICKENSON; of *Climate or Seasoning Fever*, by several writers; and of *Endemic Yellow Fever*, by others; differs from the foregoing or mild form of inflammatory fever (§ 346.) only in grade, as insisted on by JACKSON, and proved by my own observation. This is the disease which most frequently attacks new comers into the West Indies, more especially sailors and soldiers; and which has, as already stated (§ 244—247.), been confounded by recent writers with the aggravated forms of bilious fever on the one hand, and with epidemic or pestilential yellow fever on the other. It was also prevalent during the last war among the British troops and sailors in the Mediterranean, and was described by BURNETT, IRVINE, BOYLE, BRUNTON, DOWN, and others; but it generally assumed a milder form than in the West Indies.

355. Whilst the milder form of inflammatory fever is common among the white and assimilated European population of warm climates, the *severe or aggravated form* occurs among those who have more recently arrived in them, and more especially among the young, the intemperate, the robust and plethoric, and those who are exposed to the sun, to very high temperature, and to the night air. In most warm climates terrestrial exhalations are also frequently more or less concerned in the causation of the continued as well as of the remittent types of fever: the type being determined, as shown above (§ 43.), by the nature, intensity, and combination of the causes; and by circumstances peculiar to the patient, particularly the novel, or the habitual, operation of the endemic influences to which he is exposed. But, although malaria may be a concurrent cause of this fever, especially in respect of persons who have recently arrived in the West Indies, yet I believe that, where its operation is most unequivocal, the kind of fever produced by it is different from this,—premonitory and cold stages preceding reaction, which is much less violent than in this, the resulting fever being of the bilious continued form, about to be noticed.—My experience fully accords with the observation of Dr. STEVENS, that, when a young Northern stranger is subjected soon after his arrival in the West Indies to the higher ranges of temperature, his clothes are soon drenched; and that, if he be exposed to a current of air in this state, the cold produced will constrict the vessels of the skin, and prove the exciting cause of fever, which, in favourable circumstances, will often be the mild form of inflammatory fever, such as has been described above, and as is often observed in temperate climates. The causes which produce a severe affection in young and plethoric strangers, seldom affect the older residents, and never the natives of the country or the dark races. Women and children, the aged, and the weakly, are much less liable to it than the robust and plethoric.

356. *a.* The *history* of this form of fever has not been given with the requisite precision by the

various writers on it; most of them having mixed it up in their descriptions, with the inflammatory varieties of remittent, and with the more continued states of fever produced by terrestrial or vegeto-animal exhalations, concomitantly with the other causes of intertropical fevers.—The aggravated form of inflammatory fever is seldom preceded by very marked premonitory symptoms. The attack is usually sudden. Giddiness, faintness, and general uneasiness, sometimes, however, precede it for ten or twelve hours.* There is, occasionally, a slight and brief chilliness at the commencement, especially in the less violent cases, rapidly followed by a sense of universal heat; by flushed face, frontal headache, and vertigo; by inflamed, heavy eyes, and great sensibility to light and sound, by pain in the occiput, neck, back, and limbs; and by a strong, full, hard, and accelerated pulse. A sense of heat, oppression, pain, or anxiety, is felt at the præcordia, sometimes with a dry cough, and pain in the side; respiration is quick, laborious, suspirious, or anxious; the tongue is white, excited, and its edges red; the fauces are arid, thirst urgent, and skin hot and dry; the urine is scanty; the bowels costive; and there is generally nausea, but seldom vomiting until some time after the attack. If the disease be not mitigated by treatment, the patient becomes extremely restless; the headache is rending and intense; vascular action is excessive; and the heat very great. Vomiting now supervenes, and follows the ingestion of whatever is taken to allay the urgency of thirst. The matters thrown off are generally tinged with bile; and a bilious yellow suffusion of the skin is frequently observed. Bilious vomiting and purging occasionally occur with the yellowness of the surface, and, in the slighter cases, become a favourable crisis. There is often great drowsiness, but no refreshing sleep.

* Dr. MOSELEY states that there is a small degree of chilliness and horror, but never a rigor. Dr. JACKSON remarks that there is more or less of horror and shivering, but the cold is rarely great: Mr. DICKENSON, that there is increased excitement from the commencement, and that a slight chilliness at the onset is observed only in the slighter cases (§ 346.). Dr. STEVENS observes in several places, that there is no cold stage at the beginning; and Dr. BRUNTON, that languor, debility, and oppression are complained of, with chilliness.—This discrepancy in the account of the commencement of a most dangerous disease, and on a point so necessary to a knowledge of its pathology, may be in some measure explained. Dr. JACKSON has described this form of fever in connection with the more inflammatory states of remittent, from which it is perfectly distinct. The description of the other writers is more correct; for in several cases, in which I had an opportunity of observing the commencement of the disorder, no rigors, and hardly any chills, were remarked. Even some of those who complained of chills presented a warmer state of skin than natural. The pure climate fever I therefore infer does not commence with shivering or rigors; and seldom with chilliness, unless currents of air, cold, &c. have been concerned in causing it by suddenly checking the perspiration. But the continued fever attended with high vascular action, arising from malaria and atmospherical heat and vicissitudes, that is frequently met with in warm climates and in hot seasons, is commonly preceded by manifest premonitory symptoms, and by a cold stage. These two diseases, which frequently resemble each other very closely, have been generally confounded with one another, more especially as they are observed in the West Indies. Nor should this be a matter of surprise, inasmuch as that very many of the instances of fever which present themselves in men in the public services, as well as in civil life, arise from a combination of malaria with climatorial influences, and that the cases which are produced by a concurrence of such causes are perhaps more numerous than those which spring from either alone—from marsh exhalations on the one hand, or from high temperature and its vicissitudes on the other.

These symptoms of excessive excitement proceed with various degrees of violence, and occupy a period of from twenty-four to sixty hours, but most commonly from twenty-four to forty-eight hours. During this period blood taken from a vein is remarkably florid, warm, and fluid. The fibrin coagulates firmly, but the crassamentum is without crust, and is rarely cupped.

357. *B.* The excitement, having reached its acme, is quickly followed by exhaustion. This is indicated by a subsidence of the most urgent symptoms: the pain and heat are lessened; the skin becomes damp or clammy; and the patient has a sense of cold or slight chilliness. This delusive remission is a state of great danger: in some cases, it passes into rapid sinking—into a speedily fatal collapse: but, more generally, irregular determinations of blood, or indications of especial lesion of particular parts, are evinced before death ensues. With the diminution of heat and pain, the pulse falls; the countenance becomes anxious and distressed; the eyes sunk, the pupil dilated; vomiting continues without intermission, especially if the cerebral affection has abated; sometimes delirium is present, at others there is great insensibility or tendency to coma, and in these cases the stomach is more tranquil.

358. *γ.* *Discolouration* of the skin generally takes place in this stage: appearing in yellow, yellowish brown, and livid patches. It never occurs in the period of excitement, for it is quite dissimilar from the bilious yellowness occasionally observed in that period. It is commonly attended by passive hæmorrhage from the nose, gums, eyes, ears, &c., and by black and grumous vomiting. The change of colour, and hæmorrhage, proceed from exhaustion of the vital influence in the extreme vessels, and from the changes induced in the mass of blood. The matters thrown off the stomach consist at first of ingesta and serous fluid, often coloured by bile. In a more advanced stage they are ropy, mixed with numerous small shreds, flocculi, or films, which soon acquire a dark brown, purple, or black colour; but do not, at first, communicate much of the same tint to the fluid containing them. Afterwards, the matters vomited are more intimately mixed; and, from dark-coloured blood which has been effused into the stomach, vitiated bile, and other morbid secretions, assume a dark or coffee-grounds appearance. At the same time dark-coloured matter, resembling tar mixed with black blood, is freely discharged from the bowels.

359. The other symptoms characterising this stage, and preceding dissolution, are—soft quick, intermitting, or irregular pulse; clammy, cold, or partial sweats; deep and heavy respiration; coldness of the extremities; black urine, or suppression of urine; singultus, convulsive sighs; tremors and subsultus tendinum; faltering speech: low muttering or raving delirium; strugglings to get up in bed; dark or raw appearance of the tongue; livid blotches over the body, particularly the præcordia; faintings or coma, and glazed eyes.—The blood at this period is black, thin, and dissolved, its fibrin seems diminished, and it does not separate into crassamentum or serum; or if it does, the former consists of a thin dark jelly, with the black colouring matter precipitated towards the bottom of the vessel.

360. Such is the usual progress of severe in-

flamatory fever, as it fell under the author's observations, and as observed by the most eminent writers, under circumstances which seemed to preclude the influence of marsh exhalations. It has been a most prevalent and destructive disease in the West Indies and Mediterranean, during hot seasons, amongst sailors and soldiers unseasoned to these climates. It is not liable to recur; and, unlike the continued form of fever caused chiefly by malaria or marsh exhalations, it is neither preceded by, nor passes into, disease of a periodic type, nor is followed by enlargements of any of the abdominal viscera, unless the patient has been exposed to such exhalations during convalescence. A first attack prevents a second, if the individual continue in the climate which caused it; but if he return to a cold country, and reside there until the energy of his system is restored, he becomes liable, upon his return to the hot climate, to a second attack, although less so than before, and in a milder form. Numerous proofs of this position have come under my observation. This fever will not prevent those diseases which proceed from marsh exhalations; but if the person who has been seasoned by it, be seized by fever from this cause, the periodic type will be assumed, and visceral disease will frequently supervene.

361. Of a number of persons whom I treated in this fever in 1817, and who soon afterwards were exposed to marsh exhalations in their concentrated form, not one escaped agues, remittents, or dysentery.—I do not believe that this—the climate or seasoning fever—will exempt from pestilential yellow fever, although it may lessen the susceptibility to it, when the individual has not intermediately changed the climate.—Instances are numerous of seasoned persons—of those who have suffered this, the climate, or severe inflammatory fever—afterwards being seized with endemic or remittent fever, or with the pestilential disease.

362. *δ.* The *complications* of the grade of ardent fever are not so distinct as those presented by the milder form.—Some cases occur in which the *cerebral symptoms* are of greater intensity than usual, and closely resemble those of the most severe phrenitis. Such are most common in persons who have undergone much exertion whilst exposed to a very hot sun, shortly before the attack. But these symptoms, even when most violent, subside upon the supervention of exhaustion, and of the constant vomitings attending that stage.—In almost all instances, the *gastric affection* is excessive, particularly at an advanced period; but this is so characteristic of the malady, that it can hardly be called a complication. Often, however, when the cerebral affection is very great, the gastric irritability is not remarkable; and when the latter is excessive, the former is but slight.—*Biliary disorder* is sometimes very prominent, especially during the period of excitement; but it seldom amounts to more than functional disturbance—than an evacuation of bile, often in great quantity, and of morbid quality. There is evidently excited vascular action in the liver, as well as in other important viscera, but it is not actual inflammation—at least, suppuration is never observed in dissection of fatal cases. (For *Diagnosis*, see § 243—247; and *YELLOW FEVER*.)

363. *B. TERMINATIONS AND PROGNOSIS.*—*a.* Ardent or severe inflammatory fever, if not arrested

by an early and energetic antiphlogistic treatment, rapidly terminates in exhaustion of vital power with alteration of the blood, and organic change of the internal viscera, manifested especially in certain tissues.—1st. A resolution or subsidence of the excited action, without the supervention of the stage of collapse or exhaustion, seldom occurs, unless an appropriate treatment has been adopted. When the period of excitement is early and duly moderated, the severe symptoms of exhaustion either do not appear, or are very slight, debility of short duration being only present; and the patient rapidly recovers without any visceral disease. The stage of exhaustion is great in proportion to the violence of excitement, and in it the more unfavourable terminations occur.—2d. Organic change of some important organ may supervene during excitement, but rarely to an extent sufficient to produce death: it consists chiefly of vascular injection; discolouration and softening of parts; effusion of serum, lymph, or blood; and takes place most frequently within the head, and in the digestive organs. Purulent matter is never formed in this period, nor subsequently.

364. *b.* In the stage of collapse, several changes occur; but death is owing rather to their conjoint influence, than to either singly.—1st. Exhaustion of vital power is always present, but not to an extent sufficient of itself to arrest the organic functions.—2d. Deterioration or change of the blood obviously takes place, and is shown by the state of this fluid both during life and after death; but the nature of this change is not fully ascertained; whatever may be its nature, it is merely consequent upon the altered state of organic nervous influence.—3d. It is very probable that exhaustion of this influence, and the resulting changes in the blood, so affect the irritability and tonicity of fibrous and contractile structures as to impair these vital manifestations, and thereby to favour or even to induce the alterations observed towards a fatal close, particularly those affecting the capillary system and mucous tissues; for the vital tone of the extreme vessels and of the digestive mucous surface being thus impaired, and the blood being more fluid and dissolved, as well as otherwise altered, hæmorrhage readily occurs, with discolouration of the skin and of membranous parts; the blotches, &c. observed during the latter stages, proceeding from these pathological states. That the head should appear to suffer, especially during the period of excitement, is a necessary consequence of the physical relations of this part, in connection with general vascular excitement; and that the stomach and digestive mucous surface should evince predominant disorder at an advanced stage, may be ascribed to the irruption of acrid or vitiated secretions, particularly the biliary, to the state of organic nervous power, and to the changes induced in the blood.

365. *c.* The *Prognosis* entirely depends upon the period at which the disease is subjected to appropriate treatment, and upon the violence of the seizure.—When the stage of excitement has but recently commenced, the treatment about to be recommended will generally arrest the disease; but the nearer this stage approaches its acme, or that of exhaustion, the greater is the danger, as those changes in the organic nervous influence, in the blood, and in the vital tonicity of contractile parts, may be considered as having begun; and

active depletions are then not so well endured nor productive of the same effects, as at an earlier period. When symptoms of collapse appear, the danger is very great; and in proportion to the progress of this stage and the urgency of its characteristic phenomena, particularly discolouration of the skin, black vomit, and passive hæmorrhages, it becomes extreme; recovery seldom taking place when these symptoms are fully developed.—When the cerebral affection is very remarkable at an early stage, the danger is even then great, as the effects of the treatment imperatively required, conjointly with the exhaustion consequent upon excessive action, will induce a state, which, although much less dangerous than that which would indubitably follow unrestrained action, is still attended by much risk, and often requires the prudent exhibition of restoratives, &c.

366. *d.* The *Duration* of this fever varies from two to six or seven days. A fatal termination commonly takes place on the fourth or fifth day.—On examination, *post mortem*, more or less evidence of increased vascular action, often amounting to inflammation, or its consequences, is observed in the membranes of the brain, in the internal surface of the stomach and bowels, and more rarely in the pleura and serous membranes of the abdomen. The digestive mucous surface is studded with numerous dark or ecchymosed spots, from which a fluid black blood seems to ooze. The liver is frequently congested, sometimes larger and softer than natural, and of a dark colour, owing to the quantity of black blood in its vessels. The spleen is somewhat enlarged, soft, and friable; and the omentum injected.—The serous as well as the mucous surfaces, especially in the abdominal cavity, often present livid or dark patches. The blood is everywhere fluid, black, and dissolved. The internal surface of the heart and large vessels, both arteries and veins, was of a dark red or livid tint in a few cases which I examined; but this point requires further investigation, as my opportunities were not sufficient for the satisfactory examination of it in respect of the universality of its occurrence, and the exact changes on which its appearance depends.

367. *C. CAUSES.*—*a.* *Disposition to, and predisposing causes of, inflammatory fevers.*—If we view these fevers as affections of the vascular system chiefly, we may impute the disposition to become affected by them to the high irritability of the heart and arteries. As respects symptomatic fevers, this explanation may be conceded, inasmuch as the irritability of the different parts of the vascular system is derived from the same source, namely, the ganglionic nervous system; and as all causes of irritation, which act with sufficient energy, relatively to the state of irritability, upon a single part of the system, affect the whole.—I here refer the operation of the irritating causes to the state of the irritability because their action is merely relative: therefore, where the susceptibility to irritation passes beyond the usual standard, slighter causes will induce inflammatory and symptomatic fevers, than when it is either below or at the natural state. The condition of the irritability may vary not only in different individuals, but also in the same person at different epochs of life, and in the different organs of the body; the irritating causes thus exciting a relative action on different indi-

viduals, on the same person at different periods, and on the different viscera. But although the disposition to be attacked by inflammatory and symptomatic fevers depends greatly upon the state of irritability, yet the disposition to be seized by other continued fevers does not appear to arise from the same circumstance. Indeed we perceive that increased irritability of the vascular system has little or no influence in favouring the operation of the exciting causes of several continued fevers; and that other manifestations of the living organisation, besides this, dispose more remarkably to them.

363. The predisposing causes of inflammatory fevers consist, *first*, of high irritability and tonicity of fibre, more especially when conjoined with vascular fulness and imperfect performance of any of the secreting or excreting functions — of an inflammatory diathesis, or of rude health, or of a gross habit of body; — *second*, of those states of season, climate, or atmosphere, which tend to produce this diathesis. — Hence these diseases occur chiefly in young adult men; in the plethoric, florid, and robust; in persons of a sanguine and irritable temperament; in those who have experienced the suppression of an accustomed evacuation, or who live fully and richly, or intemperately, or who pursue healthy occupations in the open air, or who habitually take invigorating exercise: and they are most prevalent in cold and dry, or very warm and dry, seasons and climates; in highly elevated localities; and amongst mountaineers, sailors, soldiers, and persons living in the country.

369. *b. The exciting causes are*—(a) Whatever directly stimulates, in an inordinate manner, the nervous and vascular systems; as, change of climate, especially migration from cold or temperate, to very warm or dry countries; exposure to the rays of a warmer sun than has usually been experienced; exercise in the sun's rays; the influence of dry winds; and very dry and cold states of the air; sudden vicissitudes of weather or of season; the accumulation of electricity in the frame; a heating or very full diet, warm condiments or sauces, and stimulating liquors; change from a low to a rich or full diet; the intemperate use of wines or spirits, especially in connection with atmospheric heat or vicissitudes; great bodily exertion; violent mental excitation and emotion; — (b) Whatever indirectly induces great excitement or vascular reaction; as, the impression of cold when the body is overheated and perspiring; sleeping on the ground or in the open air, especially when exposed to the night dews, or to the moon's rays, particularly in warm and intertropical countries; the operation of marsh effluvia or malaria, especially under similar circumstances, or after intemperate indulgences; an overloaded state of the digestive organs, and obstruction of the excretions.

370. *c. The chief causes of the varieties of this fever, which attack Europeans after their migration to warm climates, are*—their early age, plethoric habits, and phlogistic diathesis; inattention to their bowels during the passage, and their use of salt provisions and spirituous or vinous liquors; increased intemperance, and incautious exposure to the sun and to the night air; excessive fatigue, or alternations of indolence and great exertion; and suppressed perspiration. Dr. JACKSON remarks that persons thus circumstanced rarely escape an

attack of fever during the first year of their residence in a tropical country; and that the fevers that occur from these causes are often of the most aggravated kind, and rapid in their course, more especially among troops crowded in barracks or transport ships, where the heat of the climate is augmented artificially; the excess of heat influencing the febrile form, increasing the violence of the symptoms, and retarding the progress of recovery.

371. A question has arisen, as to whether or not the inflammatory states of fever in warm countries are caused by malaria, or by the other causes now instanced. There can be no doubt that malaria very frequently produces in the plethoric, young, and robust, who have recently arrived in a hot climate, fever of an inflammatory and continued kind. But it must also be conceded that this fever chiefly occurs, even in persons thus constituted, during the dry season, and at times and in places where the existence of malaria is doubtful, or, at least, by no means proved. It is notoriously admitted that the inflammatory states of continued fever, in both the East and West Indies, appear among those soldiers, sailors, and civilians, who have not been long in a warm country, and who have not suffered from disease since their arrival; and that they take place chiefly during the dry and warm seasons, and in situations where the usual effects of malaria are never observed. This is the result of the experience of JACKSON, ANNESLEY, BOYLE, TWING, CONWELL, and of other experienced practitioners in warm countries. It agrees with my own observations; and is even admitted by Dr. FERGUSON, who has gone much further than any one else in assigning malaria as the cause of intertropical fevers. I believe that the other causes assigned above (§ 367—370.) will, in these countries especially, produce fever of an inflammatory or bilio-inflammatory kind, in unacclimated Europeans; but that, when those causes are not associated with malaria, the fever resulting from them will generally subside, under judicious treatment, without evincing those dangerous symptoms which characterise fevers proceeding chiefly from terrestrial exhalations. Although some of the causes, especially those which relate to atmospheric temperature and climate, are very different as to their nature and action, yet they are mainly instrumental in producing fevers having many common features, but differing in severity and duration.

372. *D. NATURE OF THE DISEASE.*—Fever produced by paludal miasms, or by infectious emanations from living or dead animal matter, are universally preceded by well-marked symptoms, characteristic of the stages of *premonition* (§ 33.) and of *invasion* (§ 35.). But inflammatory fever, especially in its more severe form, is seldom preceded by more than chills, unless cold, or other causes which suddenly arrest the cutaneous excretions, have been concerned in producing it. In these fevers a poisonous agent has infected the frame and more or less depressed its vital energies, particularly as they are manifested in the organic nervous system; vascular reaction being consequent upon such depression, as shown above (§ 95, 96.). But in this fever, the injurious agent, or primary pathological change, is generated within the system from the action of new and unwanted

influences, generally climatorial or atmospheric. That this agent is not of a depressing kind, as respects its primary operation, is manifest, from the general absence, at the commencement of the disease, of those phenomena which indicate this kind of action. That it is of an irritating or exciting kind, may be inferred, not merely from the character of the invading symptoms, but also from the changes primarily induced by the remote causes. — If we inquire into the nature of these changes, we shall find them — 1st, As respects the *mild inflammatory fevers* of cold or temperate climates, to consist — (a) of the organic and nervous excitement consequent upon the rapid and increased oxygenation of the blood during cold and dry states of the air, probably aided by the accumulations of the electro-motive agencies in the system which these states manifestly favour; — (b) of the super-abundance of irritating matters in the circulating fluids resulting from casual interruptions to one or more of the eliminating or depurating processes constantly going on in the animal economy; — (c) of the combination of these circumstances or primary pathological condition. If we grant that the former of these obtains, it is very obvious that the occurrence of the latter will further excite and increase it; even a susceptibility to the former, as marked by high irritability of fibre, may be readily kindled into morbidly increased action, by causes of irritation which may have accumulated either within the vessels — in the blood itself; or external to them — in excreting organs and surfaces. These pathological states are the obvious results of concurrent causes, which primarily excite the sensible and susceptible parts of the frame, and which retard or prevent the discharge of irritating materials from the vital currents which supply and sustain these parts; the accumulation of these materials either increasing the excitement, or giving rise to it. It must necessarily follow that the excitation thus induced will exhaust itself to a degree, and with a rapidity, co-ordinate with its intensity, and thereby induce the phenomena characterising the advanced periods of the disease, which are especially remarkable in the severe or climate fever of warm countries.

373. 2d. As respects the *severe inflammatory or climate fever*, the procession of phenomena must necessarily be different, as it generally arises from causes different, or even opposite, to those just instanced — from a very high temperature, often conjoined with rich, nutritious, and heating food, stimulating drinks, and suppressed perspiration. Either of these is alone sufficient to induce the disease; but, when they co-operate, the effect is more certain and severe. They all act in a similar manner: they excite the organic nervous system inordinately; increase the actions of the liver, and irritate its vessels; alter the constitution of the blood, causing it to abound with stimulating and injurious materials; and render the secretions and excretions acrid or morbidly exciting. Thus the most violent states of this fever often proceed directly from these causes, without any evidence of primary subaction or a cold stage, unless depressing agents, such as cold, human effluvia, or malaria, concur with them in producing disease; in which case the consequent fever will present features modified accordingly. If cold act upon persons who are under the influence of these ex-

citating causes, a slightly cold stage will often be directly induced thereby. If animal or vegetable miasms concur with them, the fever will present adynamic or malignant characters in proportion to the activity of either of these agents. But when the above direct causes of excitement act solely or principally, their influence upon the organic nervous system is very energetically expressed, and manifested throughout the vascular system, especially that of the brain, liver, and digestive mucous surface. Thus, inflammatory fever differs from the other varieties of idiopathic fever — 1st, in its proceeding from causes, the primary action of which is exciting or irritating; 2d, in excitement or irritation being more or less evinced by it from the commencement.

374. Of the changes that take place in the advanced period of the disease, the most remarkable are those affecting the blood and the digestive organs. As the stage of excitement merges into that of exhaustion, the blood changes from a florid to a dark colour; loses its property of separating into crassamentum and serum, and of firmly coagulating; becomes more fluid; and seems deprived of much of its fibrinous and albuminous constituents. (See art. BLOOD, § 128.). According to Dr. STEVENS, its saline ingredients are also greatly diminished. The chief cause of these alterations is evidently exhausted organic, nervous, or vital power; and this is further evinced by a loss of the tone of the extreme vessels, and of the irritability of the moving fibre, always co-ordinately observed in cases presenting this change in the blood. Among the most striking consequences of exhaustion of vital power, as thus manifested in the extreme vessels and blood, are, discolouration of the skin, and passive hæmorrhages from mucous surfaces — phenomena characterising the last stage of the most unfavourable cases of the intense disease. The gastric disturbance in the early stages generally proceeds from excited vascular action, and from the passage of irritating secretions into the stomach, in connection with an increased susceptibility and irritability of the organ. In the latter stages, it more especially results from the morbid secretions poured into the stomach, and the irritated or inflamed state of its villous surface.

375. The source of the black matter passed from the stomach and bowels in the last stage of this and of other severe fevers of warm countries, has been variously stated. Some consider the black colour to proceed from the exudation of dark blood, which, in mixing with the secretions of the stomach, liver, and bowels, imparts to them a still darker tint. Some ascribe it chiefly to the bile, and secretions from the digestive mucous follicles, which are often both very dark and thick in the last stage of the more malignant kinds of intertropical fevers; and others believe it to arise both ways. There is no doubt that all the secretions poured into the digestive canal are more or less diseased, particularly in the latter stages; but it is as clear, that the black colour mainly depends upon the state of the blood; and that all the matter ejected upwards and downwards, presenting this appearance, does not consist of altered secretions merely, — a great part of it probably being an exudation of blood from the mucous surface. I believe, also, that these matters vary very remarkably in the ardent climate fever, in the more malignant forms

of marsh or endemic fevers, and in the pestilential yellow fever—the diseases thus characterised. Dr. JACKSON remarks that the secretions from the digestive mucous surface are ropy and clear during the early periods, and are brown or black in the latter—sometimes black as soot; and that the sooty or ink-like colour is chiefly observed where the head and stomach are simultaneously attacked. When we consider that the blood becomes darker than natural, as well as otherwise changed, early in the period of exhaustion, and that the liver and mucous follicles of the digestive canal, with the kidneys, are the principal organs of depuration, or channels by which the elements producing these changes are eliminated from the circulation, we need not be surprised at the secretions which these elements go to form, and which these organs excrete, presenting somewhat similar characters. It must however be admitted, that the share which the secretions perform in producing this phenomenon, or that which the exudation of blood has in giving rise to it, will vary much in different varieties or cases of intertropical fevers.—The rapidity with which a dissolution of the tissues takes place after death, in the severe forms of climate fever, deserves notice, as marking the rapidity of vital exhaustion, and as resulting from the changes of the blood; these changes commencing with the stage of exhaustion, and advancing until this fluid is no longer capable of influencing the nervous system, and of preserving the irritability of contractile parts—or until it poisons, instead of exciting, the sensitive and moving tissues.

376. E. TREATMENT.—The means that should be employed in the *mild* and *severe* forms of inflammatory fever are the same—the only difference being in the promptitude and energy with which they ought to be administered. In the mild disease, particularly in cold or temperate climates, the febrile excitement is much more prolonged than in the severe, which rapidly exhausts itself by its violence. The necessity, therefore, of restraining it at its commencement is great in proportion to its activity. In the milder forms, vascular excitement may continue several days, and depletions may be practised with advantage as long as this state persists; but, in the severe, the period in which they can be employed with benefit passes away sometimes in a few hours; and continues seldom beyond the third, and rarely beyond the fourth day. As in the state of excitement, so in that of exhaustion, the treatment is the same in all the varieties of this fever—the only difference being in the choice of means, in the activity with which they should be employed, and in the appropriation of them to the varying circumstances of the case.

377. a.—a. During excitement, and especially at its commencement, vascular depletions should be practised, and carried as far as the state of the pulse and other circumstances will permit; and in the manner described in the article BLOOD (§ 64.). The observations already made on this subject (§ 128—138.) will guide the inexperienced practitioner; but it should not be overlooked, that, in the intense climate fever, vascular depletion should be prompt, from a large orifice, large, and repeated, to be successful; and that the quantity of blood abstracted should depend chiefly upon the effect produced. Dr. JACKSON justly remarks that it should be taken in quantity

sufficient—whatever may be the amount—to relax the surface and set free the secretions. Less than three pounds is rarely sufficient to produce this effect; and six have not been more than sufficient on some occasions: but whatever the amount may be, it will do comparatively little good if we stop short of the quantity which is requisite to effect a decided change. If delayed until the excitement is about to terminate in exhaustion, no benefit—or even mischief—may result from it; for the tonic of the vascular system will have then become too far weakened to admit of the vessels accommodating themselves to a considerable loss of blood. When, therefore, the symptoms indicating the passage of excitement into collapse, or the deceptive abatement of the febrile action indicating this state, is observed—and particularly if yellowish blotches appear about the mouth, face, or breast—the time for bleeding with advantage has passed. If, however, headach is still urgent, the pulse still strong, and the features have not collapsed, blood may yet be abstracted cautiously and in moderation. When the cerebral affection is considerable or persistent, and is unattended by marked symptoms of exhaustion, depletion, general or local, may be repeated. Where the headach is particularly intense—rending, throbbing, &c.—with hot inflamed eyes, one bloodletting, however large or early, will seldom be sufficient. In such cases, the body should be immersed in a tepid, or slightly warm, bath, and well scrubbed with brushes, &c., until the cutaneous circulation is rendered free. Cold should also be applied to the head, both during the bath, and subsequently, the hair having been cut off. After the patient is removed to bed, the vascular action and headach will often become again excessive; and, although a very few hours only may have elapsed, will require the repetition of very large depletions. Spontaneous hæmorrhage during excitement should not be arrested. In the most severe cases, especially when determination to the brain is great, epistaxis often occurs, but is generally slight, or almost instantly disappears. In these, vascular depletions, aided by the other means appropriate to this state, ought to be most energetically practised; for nothing else will save from fatal changes taking place within the brain, or from as fatal exhaustion, and its effects.

378. b. Purgatives, in one form or other, are a material part of the subsequent means. Calomel with jalap and James's powder may be given, in the form of pill, from time to time; and, after a few doses have been taken, a cathartic enema should be administered, and repeated. As to the choice of the enema, the practitioner should be guided by the progress the disease has made. At an early period, sea water, with or without the addition of castor oil, or of extract of colocynth, is appropriate: subsequently, olive oil and oil of turpentine may be substituted for the latter.—Emetics are not suited to any state of this fever; although they are often serviceable in fevers which have been confounded with it, more especially at the commencement of the various forms of marsh fever.

379. γ. Refrigerants, when judiciously exhibited, are valuable adjuncts in the period of excitement. Those already enumerated, both *internal* and *external* (§ 139—141.), should be perseveringly em-

ployed. Of these, the *nitrate of potash*, the *nitrate of soda*, and *hydrochlorate of ammonia*, and injections of *cold sea water*, as recommended by Mr. DICKENSON, are most deserving of notice. HILLARY prescribed a scruple of nitre and twelve grains of hydrochlorate of ammonia, three or four times a day, in water; and Dr. CONWELL has recently shown the propriety of this practice, and its applicability to other states of febrile action. In the more ardent climate fever, this medicine should be very frequently exhibited during excitement; cold applications to the head, and the cold affusion being also assiduously employed. The refrigerants just mentioned may likewise be taken frequently in conjunction with the *liquor ammonia acetatis* and *spiritus aetheris nitrici*. After depletions, they will often prevent the distressing irritability of the stomach, which increases with the unfavourable progress of the disease, and allay it when present. Although this is the most violent form of fever which comes before the physician, yet it may be arrested at an early period with greater certainty than any other, by the decided employment of the foregoing measures.

380. *δ. External derivatives*, and more particularly *blisters*, have been very much employed against the inflammatory forms of fever, with the view of allaying the irritability of the stomach, and protecting it and other viscera from impending injury. But I believe that they have been as often injurious as beneficial; and that, owing to a too early use of them, they have increased the general excitement, and not derived from internal parts. It is only after vascular action is subdued as low as may safely be attempted, by the foregoing treatment, that *blisters** should be employed in this disease; but they ought never

* The following case will show the progress of the disease, as well as its cerebral complication, in its most severe form; and the little effect which a depletory practice, short of what it requires, produces upon it.

A soldier of a full and gross habit of body, aged 28, just arrived in the West Indies, during the hot and dry season, was attacked, at six o'clock in the morning, with giddiness, severe headach, and pain in the back and limbs. He came under treatment at six in the evening (twelve hours after the attack), and then these symptoms were violent; the face was flushed, the eyes heavy and injected; the breathing was laboured; the pulse frequent, sharp, and contracted; the heat great, and skin dry; thirst vehement; tongue white and foul. He was anxious, restless, and complained of oppression at the præcordia. He was bled to thirty-two ounces: a purging bolus was given immediately, repeated in four hours, and accelerated by an enema. He seemed a little faint from the bleeding, and expressed ease, but no decided relief. He passed the following night in much distress.

Second day of disease, in the morning, he complained of anxiety and uneasiness at the præcordia; sighed frequently, and breathed with catching and difficulty at times. Pulse quick, hard, and strong; the skin very hot and dry; intense pain in the head and loins. Bowels not freely opened by the purgatives. Was bled to fourteen ounces: the skin became moist; the pains remitted, but did not cease. Blisters to the head and epigastrium; calomel and James's powder every third hour; inunction with mercurial ointment; saline diaphoretics. He sweated copiously in the afternoon, had some evacuations by stool, and seemed relieved.

Third day.—Anxiety and sense of burning at the præcordia; nausea and vomiting; ineffective motions downwards; skin dry; pulse strong, not frequent; thirst urgent; eye and countenance lurid; temper irritable and impatient; alarmed at his situation; complains of the blisters on his head, which give sensations of burning. The skin is dry, and the heat rather above natural. The tongue is somewhat rough and foul.

Fourth day.—Symptoms more unfavourable. He vomits occasionally, and his nose bled in the act of vomiting; anxious, restless, and very uneasy. Pulse regular, full, and strong; ideas confused; countenance irregularly tinged yellow.

to be applied on the head; unless in the stage of exhaustion, when coma or lethargy is present, and the pulse becomes weak and intermittent. The exhibition of *mercurials* with the view of inducing salivation should not be attempted in this fever; for this effect has never been produced unless in the milder cases, which would have recovered nevertheless.

381. *b. The period of exhaustion* presents comparatively few chances of recovery, especially when far advanced, and in severe cases; but these few should not be thrown away, either by a temporising or a trifling practice; or by the use of means already known to be unavailing. There can be no doubt, that the change commencing in the blood with the accession of this stage is one of the chief pathological states which should attract the attention of the practitioner; but the exact nature of that change has not been satisfactorily demonstrated. That it partly consists of diminished crisis, or a weakened vital attraction between the globules of the blood, and con-

Fifth day.—Somewhat delirious; extremely restless and anxious; eyes red and muddy; gums red and hot; no salivation; pulse regular, full, but not weak; skin dry and of a deep yellowish shade; the blistered surfaces dry and of a dark red approaching to a livid hue. He was washed with salt and water. Frequent small dark viscous evacuations.

Sixth day.—Delirious, with extreme restlessness; pulse soft, full, and slow; skin damp and clammy; heat moderate; vomits glutinous matter of a black colour; dark blotches in the skin; and a black sanies exudes from the nose and mouth.—He died in the afternoon, five days and twelve hours from the attack.

Dissection.—The vessels on the surface of the brain were remarkably turgid, giving a livid appearance to several places. Considerable effusion of lymph, and adhesions between the membranes had taken place, particularly near the falx. The stomach and intestines contained a large quantity of black matter. In the latter, it was thick as tar, and viscous as birdlime. The gall-bladder was half full of black bile.

Remarks.—The above case was not treated by the author. Twelve hours were lost before the patient received assistance. On the second day the bleeding was insufficient, and should have been carried further and repeated. The pulse evinced the necessity of it. In this disease, as in many others, the pulse may be safely followed. If the pulse become an unsafe guide, the fault is most generally that of the observer, who cannot interpret it aright. The application of two blisters at this time, before vascular action was sufficiently reduced, and more especially the application of one of them to the head, during predominant action in this quarter, was sealing the fate of the patient,—the bleeding in the first instance being just sufficient to give freedom to the circulation, but not adequate to reduce it; the blister adding fuel to the fire when it was about reaching its height. The inunction of mercurial ointment with the view of affecting the system was as fruitless, and just as rational, as respects this fever, as to attempt to extinguish a conflagration by a surgeon's syringe. On the *third day*, the great strength of pulse, and burning sensations in the head and præcordia, clearly indicated that large bloodlettings could alone have saved the patient, although late in the disease. The local complication, having prevented the sudden accession of this stage, and prolonged vascular excitement, admitted of a later recourse to depletions than in other circumstances. Even on the *fourth day*, owing to the cerebral complication, the pulse retained its strength, and, with all the other symptoms, evinced that bleeding should even then have been practised. After the first day nothing appropriate was done but much to aggravate the disease. As to the *dissection*, the usual routine only was gone through, and which, if pursued in a million of cases, would not advance our knowledge of the disease one step. The symptoms on the second and third days ought to have suggested a minute examination of the vascular system and blood; but these, as well as the digestive mucous surface, were unexplored. In this case, as in many others, the name of the disease, contradictory opinions as to its nature and origin, and empirical reports of successful methods of cure, misled the practitioner, and paralysed the treatment, when he ought to have been guided by a knowledge of morbid actions, and of rational means of removing them.

sequently of a defective power of coagulating, and of altered colour, has been shown by TOWNE, and by every writer since his time, and is generally admitted: but the observations of Dr. STEVENS, as to the progressive loss of saline ingredients, which the blood undergoes with the progress of exhaustion, although now published several years, have not received that confirmation, for which there have been sufficient time and opportunity. They are not, however, therefore, altogether to be thrown aside, more especially as my experience has furnished me with facts calculated to support them in some measure. The exhaustion in this disease arises, — 1st, from the previous excitement; and 2dly, from the changes induced in the blood in the course of this stage; especially at its acme, manifestly depressing the organic nervous influence, the tonicity of the vascular system, and the action of the heart itself, to an extent often incompatible with the continuance of life. It is in this manner that death generally takes place in the intense climate fever; for, however considerable the lesions are which the early excitement had occasioned in the brain or digestive organs, death is seldom the result of them alone in either of those parts. It should, moreover, be recollected that the disease cannot be cured by bloodletting merely, however necessary it may be to the subduing of excitement in the early stage; for although this state may be lowered by it, still dangerous exhaustion may nevertheless supervene with the characteristic changes of the blood, and all the consequent phenomena described by the earlier writers on this fever, particularly by TOWNE, WARREN, HUME, LINING, HILLARY, &c.

382. *a.* From these considerations it is manifest that the *intentions of cure*, in this stage of the disease, should be — 1st, to support or rally the manifestations of life in the different organs — to oppose the progressive vital exhaustion; 2dly, to counteract those changes which take place in the blood and vascular system. These indications should be simultaneously carried into effect; for the alterations in the state of vascular action and tone, as well as in the constitution of the blood, are more or less dependent upon the change in the organic nervous influence. — At the commencement of this period, and when vascular action still continues high in the encephalon or digestive mucous surface, a moderate local depletion may precede measures calculated to fulfil these intentions; but even this form of depletion can seldom be carried far; for the tonicity of the vascular system generally, and especially of the capillaries supplying the mucous surfaces, is too far exhausted to admit of that accommodation of the vessels to a considerable diminution of their contents, which is so requisite to the restoration of a healthy state of circulation. The characteristic phenomena of the last stage — the hæmorrhages and discoloured blotches — are manifestly owing as much to the exhaustion of organic nervous influence and of irritability, as to the attendant changes in the blood. It is to these latter changes almost solely that Dr. STEVENS directs his means of cure in this stage; but it is evident that the vital conditions on which they depend should receive equal attention. He states that the quantity of the chloride of sodium is greatly diminished in the last stage of this and other malignant diseases;

and that, in order to supply the deficiency, he at first gave a strong solution of this salt with nitrate of potash. He subsequently found that the chlorate of potash and other active saline agents answer the purpose equally well, especially those which do not irritate the stomach; and he now seems to prefer a combination of the chloride of sodium carbonate of soda and chlorate of potash. The basis of this pathology and treatment is the relation subsisting between the colour of the blood and the saline matters contained in it. The power of certain salts, particularly the chloride of sodium, the nitrate of potash, the tartrate of potash, &c., as well as of the alkaline carbonates, to render the venous blood florid, and to affect its fluidity and coagulating powers, was long since fully demonstrated by VERHEYEN (vol. ii. p. 29.). SCHWENKE (*Hæmatologia*, p. 190. *et passim*), HALES (*Hæmostat.* p. 154.), ELLER (*Mém. de l'Acad. des Sc. de Berlin*, t. vii. p. 13.), BOERHAAVE (*Elementa Chymia*, t. ii. p. 378.), PETIT (*Lettre Seconde*, p. 34.), HALLER (*Elementa Physiol.* t. ii. p. 74.), SAUVAGES (*Sur l'Effet des Médicaments*, p. 37.), and others. A combination of the nitrate of potash and of the hydrochlorate of ammonia was always employed by HILLARY in this disease, and is applicable to every period of it. Sea water has long been a popular remedy for it and other West Indian fevers, and is very strongly recommended by AREJULA and Mr. N. DICKENSON as an enema. Dr. CHISHOLM employed, in 1798, the chlorate of potash, and remarked its effects upon the blood; but, as Dr. STEVENS justly states; he exhibited other substances calculated to counteract its influence on the disease. But granting that the colour of the blood is changed to its healthy state by these salts, it does not follow either that they shall be absorbed into the circulation during the advanced stage of this fever, or that they shall have the effect of rallying the exhausted powers of life. As to both these circumstances, the sanguine expectations of Dr. STEVENS require confirmation. There can be no doubt that, to be serviceable, these medicines should be given sufficiently early in the exhaustion to allow time for their absorption; and that substances which irritate the digestive mucous surface, and prevent or delay absorption, should not also be exhibited. In the present state of our knowledge, and judging from some experience of the effects of these salts in the advanced stages of other severe fevers, I infer that they ought not to be confided in alone, but should be conjoined with such other means as are calculated to rally or support the vital manifestations, and promote the excreting functions — always recollecting that, in order to preserve the blood in a state suitable to the continuance of life, the depurative actions of the various emunctories require to be promoted.

383. *β.* In the early stage of exhaustion, HILLARY'S saline mixture may be prescribed; or the same salts — the nitrate of potash and hydrochlorate of ammonia — may be given in camphor julap; the quantity of camphor being regulated according to the grade of depression. The chlorate of potash may likewise be given in the same vehicle; or the citrate or tartrate of potash or soda, with an excess of the alkali. It is very important, to avoid such means as will increase the irritability of stomach characterising this stage of the disease; and I believe that these medicines are much less

likely to have this effect than almost any other. A full dose of *calomel* will often have the effect of allaying for a while the irritable state of this viscus; but, when exhaustion is very considerable, its sedative influence on the organic nervous energy will be injurious, if it be not combined with camphor or ammonia. During the course of this stage, little benefit will accrue from such purgatives as irritate the stomach. An occasional Seidlitz powder, or the saline medicines just mentioned, assisted by frequent injections of sea or salt water, with the addition of an ounce or two of sweet oil, will prove much more serviceable than more active means, which will only increase the inflammatory irritation of the digestive mucous surface, and exhaust its vitality. Dr. JACKSON most frequently prescribed a combination of *calomel*, James's powder, nitre, sulphur, and soda, in the form of bolus, which was given every fourth hour; and afterwards the infusion of senna, with liquor ammonia acetatis, so as sufficiently to promote the action of the bowels.

384. γ . In a further advanced state, and more especially if the pulse become irregular or intermittent, the more energetic restorative and nerve medicines should be prescribed, variously combined with one another, or with the saline substances just mentioned. Warm or rubefacient epithems, or sinapisms, should be also applied over the epigastrium, or to the lower extremities; and hot wine with spices; or champagne; or large doses of camphor with nitrate or chlorate of potash; or brandy and water, as the vehicle of effervescent salts; or half drachm doses of turpentine, every two hours, in milk, or in spruce or ginger beer, may be resorted to, according to circumstances. But, before the exhaustion has proceeded thus far, these remedies, in more moderate doses; the preparations of ammonia, conjoined with saline or other medicines, the warm bath, &c.; may be employed, with a cautious observation of their effects. — Upon the whole, the principles developed above, in respect of the treatment of exhaustion of vital power in fever (§ 143—148.) should be adhered to.

385. δ . During the progress of the stage of exhaustion, much attention ought to be directed to the beverage of the patient. Spruce beer, soda water, Seltzer water, bottled porter, bottled small beer, may be allowed, but only in small quantity at a time, as a considerable draught is generally followed by vomiting. These beverages may, moreover, be made the vehicle for the exhibition of refrigerant, antacid, or saline medicines, as the nitrate of potash, the alkaline carbonates, &c. During *convalescence*, the diet should be carefully regulated, and confined at first to farinaceous articles, in moderate quantity.

386. *c*. The modified form of *inflammatory continued fever*, arising from the concurrence of terrestrial exhalations, with climatic influence, must be treated, in the periods of excitement and of exhaustion, conformably with the views explained above. This form of fever, after the inflammatory excitement is subdued by copious depletions, sometimes assumes a remittent character. In this case, the exhibition of bark or the sulphate of quinine during the remissions will be necessary. Whatever *complication*, also, which may either characterize this fever from its commencement, or appear in its course, must be

treated by depletions, local especially, and derivatives, according to the principles already advocated. — (See BILIO-GASTRIC FEVER.)

387. DEFIN. — *Vascular reaction following chills or rigors and other symptoms of premonition and invasion, with predominant affection of the biliary functions, and of the digestive mucous surface, frequently with yellowness of the skin, in the severer cases.*

388. This fever is either sporadic, endemic, or epidemic. — It is endemic in warm countries and marshy situations among Europeans, particularly those who have not been long resident in these parts; and in marshy localities in the summer and autumn, in temperate climates. — It is epidemic in some seasons, particularly in autumn when the summer has been hot, after a wet spring, or after great falls of rain, or after inundations, and when great numbers of predisposed persons, especially from high latitudes, visit such localities. In these circumstances and persons, it proves the

seasoning fever. It is observed chiefly in adults of the bilious or bilio-sanguine temperaments, and in persons addicted to spirituous liquors. It is a very prevalent fever in the countries bordering on the Mediterranean, in the East Indies, and in America, and consequently in fleets and armies in these parts.

389. i. DESCRIPTION.—This fever, in robust and plethoric persons, approaches severe inflammatory fever on the one hand, and the more inflammatory forms of remittent on the other: or it presents a predominance of the characters of either, according to the intensity of the causes and the peculiar circumstances of the affected. The chief difference between inflammatory fever and it, depends upon the causes whence they respectively proceed; the former arising principally from atmospheric vicissitudes and climatorial influence, in connection with suppressed perspiration; the latter chiefly from marsh and vegeto-animal miasms (see *Diagnosis*). Its similarity to, and connection with, remittents, are referrible to the origin of both in the same causes; the only differences between them resulting from the intensity and concurrence of the causes, and from individual predisposition—being differences chiefly of grade and of type, as shown by Dr. BOYD, and confirmed by my own observation. That it should therefore be confounded with these fevers, cannot be a matter of surprise, and is of little importance as respects the treatment. But when it is mistaken for the synochoid and adynamic species with predominant affection of the digestive mucous surface, then the results may be serious.

390. A. *Gastro-bilious fever* is generally preceded by lassitude, nausea, or want of appetite; by dull pains in the back and limbs; and by flatulence and indigestion. The breath is fetid; the tongue is covered by a yellowish mucous coating; the mouth is clammy, and the taste perverted; the bowels are costive, or relaxed, or irregular; and the countenance is pale or somewhat sunk. This state—the *premonitory stage*—may continue several days, the patient not being confined to bed; but generally in the morning he is seized with chills or rigors, preceded by a sensation of cold creeping along the spine. To these soon succeed severe frontal headach, vertigo, nausea, vomiting, burning heat of skin, restlessness, watchfulness, slight anxiety at the præcordia, pain and oppression in the epigastrium, and in one or both hypochondria, with more or less soreness, fulness and tenderness. The eyes are moist and injected, the conjunctiva often yellowish; the face is flushed; the breathing oppressed and accelerated; the pulse full, large, quick, and strong, rarely hard; the tongue is clammy, moist, furred, and yellowish, with a bitter taste in the mouth; the thirst is urgent, the breath fetid; the bowels are obstinately costive, or loose; the stools bilious, and the urine scanty and dark. When the stomach and bowels are inordinately affected, cerebral congestion very frequently supervenes at a later period. As the disease advances, the pulse feels less full, and is weaker than in health. The thirst and anxiety are increased; and the upper parts of the body are sometimes covered by a profuse sweat, whilst the skin still continues hot.

391. If the attack be very severe, or neglected at the commencement of reaction, the pain of the head is aggravated; and a disinclination to

answer questions, stupor, and insensibility appear about the second or third day. The eyes are turgid or inflamed; a bilious yellow tinge spreads from the face downwards over the body; the tongue is covered by a thick yellow crust, is red at its sides, and dry and brown in the centre; the strength is diminished; nausea with bilious vomiting is often distressing; the pulse becomes weaker and quicker; and the patient has an insatiable thirst, and desire of cold acidulated fluids. The urine is very high coloured, voided often, and produces scalding in passing it. The bowels are either costive or loose.

392. If the disease has not been mitigated, a slight remission occurs on the third, fourth, or fifth day, generally in the morning; the face and chest being covered by perspiration, and the temperature of the surface reduced. But the symptoms are exasperated towards evening; the tongue becoming drier and darker; the epigastrium and hypochondria more painful, tender, and often also tumid and tense; the pulse more rapid, constricted, or weak. The anxiety at the præcordia is now changed into severe pain, aggravated on pressure, with oppression and frequent sighing; the countenance is sunk; there is vomiting of putrid or offensive bile; the stools are liquid, greenish brown, fetid, slimy, and occasionally bloody or dysenteric; the skin is often deeply jaundiced, and emits a putrid bilious odour. The patient is now collected, but various adynamic and malignant symptoms appear from the fifth to the seventh or eighth day. These are—tremors of the extremities, and of the tongue when held out; startings of the tendons; pain about the pubes, with inability to pass the urine; vomiting of a dark, glairy matter; difficulty of swallowing; sometimes swelling and suppuration of the parotid glands; tympanitic distension of the abdomen; inexpressive, glassy eyes, dilated pupils; clammy sweats, difficult and anxious breathing, and black tongue. To these succeed delirium, coma, intermitting pulse, cold extremities, and death, sometimes with convulsions. Petechiæ, blotches, and passive discharges of blood from the nostrils, gums, fauces, &c., are but rarely observed.

393. B. *Modifications*.—All the above symptoms are not present in the same case, nor always run the same course. In the young, strong, plethoric and unseasoned, in the sanguine and intemperate, and in very hot and dry seasons, this disease approaches very closely to severe inflammatory fever (§ 354.) with predominant affection of the stomach and membranes of the brain, or of the digestive mucous surface generally. But in weak or elderly persons, and in colder climates and seasons, it is more mild, and approaches, or even runs into, some one of the varieties of remittent. Indeed, it may assume either *inflammatory* or *adynamic* characters, or present *complications* similar to those observed in that fever, from which it differs merely in type. When animal miasms and infection are associated with the other causes, as in crowded transports, ships of war, prisons, camps, &c., in warm climates, or in hot seasons, more or less adynamia or depression of vital power, with contamination of the circulating fluids, is evinced early in the disease—*malignant* and nervous symptoms predominating towards the close. In such cases, the premonitory and invading stages are very manifest; reaction is

often low or imperfect, as in the more adynamic states of remittent, or rather in the malignant form of fever about to be noticed; and the type is perfectly continued. But when it arises chiefly from terrestrial exhalations, the circulating and secreted fluids are less vitiated, and it presents more of the remitting character. When these causes are very intense, and the predisposition great, the disease often assumes a very *concentrated* and *acute* form, runs its course rapidly, and often passes into the remitting type, or induces visceral disease. These violent states of bilio-gastric fever have been often met by Mr. BOYLE and myself in Africa, and by Dr. J. JOHNSON, ANNESLY, and others in the East Indies. This fever thus may resemble, according to the nature of the causes—predisposing and exciting,—of the seasons, of the locality and climate, and of the epidemic constitution, either inflammatory, or remittent fever, or even malignant fever—may possess more or less of a gastric character in one case, of a bilious state in another, of an inflammatory condition in a third, of cerebral affection in a fourth, of an adynamic or malignant form in a fifth, or a predominance of any two or more of them. These modifications give rise to the appellations, gastric, bilious, yellow, gastro-bilious, gastro-inflammatory, bilious inflammatory, bilious continued, gastro-meningitic, &c., applied to it by modern writers, and cause it frequently to be confounded with the severe inflammatory fever on the one hand, and with pestilential yellow fever on the other.

394. ii. DURATION AND TERMINATION.—These depend upon various circumstances—chiefly upon the exciting causes and circumstances proper to the patient.—*a.* When judiciously treated at an early stage, a favourable change generally appears from the third to the seventh day, or even earlier.—*b.* But when the disease has been neglected, or aggravated by improper means, *death* may take place from the fifth to the eighth day, preceded by the unfavourable signs just enumerated (§ 393.). In these, the brain or its membranes, or the digestive mucous surface, or all of them, have suffered very considerably, and are more or less changed.—*c.* In some cases, and when it is occasioned by the concurrence of marsh exhalations with the other causes enumerated above, more particularly in hot climates, or in temperate countries during warm summers and autumns, the inflammatory action extends to the mucous surface of the small intestines and large bowels, the disease terminating either in enteritis or acute dysentery. As in the remittent type, so in this, the state of the secretions, particularly the biliary, and the nature of the ingesta, concur with the exciting causes in developing these complications (§ 237.). *d.* The fever may also pass into *inflammation* or abscess of the liver. This is a frequent complication and termination of the bilio-gastric fever of the East Indies, and of some other inter-tropical countries. When abscess forms in the liver in these cases, dysenteric symptoms are often superadded.—*e.* When the disease has not been entirely arrested, but only mitigated by treatment, or when it has been mild at the commencement, and caused chiefly by terrestrial exhalations, the patient continuing subjected to their influence, it may pass into a *remittent*, or

even an intermittent type. In such cases, enlargements of the spleen, of the liver, of the pancreas, and even of the mesenteric glands, may ultimately supervene.—*f.* *Relapses* are more frequent in this than in almost any other fever, and are caused chiefly by a too early recourse to a full or stimulating diet, by irregularities in food or drink, by incautious exposure to the night air or to cold, by vicissitudes of temperature or of season, and by terrestrial or vegetable miasms.—The *lesions* observed in *fatal cases* are altogether similar to those found in the more inflammatory and severe forms of remittent.

395. iii. DIAGNOSIS.—*Bilio-gastric* fever nearly resembles—1st. *Inflammatory fever*, in its milder states;—2d. *Remittent fever*, in its severe forms; and, 3d. *Epidemic* or *pestilential yellow fever*.—*a.* From the *first*, it is distinguished by premonitory symptoms of considerable severity and continuance; by the marked chills and rigors characterising its invasion; by the early occurrence of nausea and bilious vomiting; by the less continued and violent state of vascular reaction; by the copious and early bilious evacuations and the bilious suffusion of the skin; and by the usually longer duration of the disease. In severe climate or inflammatory fever, on the other hand, the invasion is sudden, and vascular action more or less excited from the commencement—premonitory symptoms being hardly observed. Subsequently the blood undergoes a much more remarkable change than in gastric fever—the yellow and livid blotches appearing in the last stage, being very different from the bilious suffusion of this disease; and the hæmorrhage from the mucous surface, the black vomit, and dissolution of the fluids, &c., so frequent in the former, being neither so common nor so great in the latter. The pain in, and determination to, the head, is more severe in the first stage of inflammatory fever, and the disorder of the stomach much less than in gastro-bilious fever; but the affection of the stomach becomes more violent and unremitting at an advanced stage of the former than of the latter.

396. *b.* Gastro-bilious fever is distinguished from *remittent fever* chiefly by its continued or imperfectly remitting course. In other respects there is little difference between it and the severer forms (§ 230. 232.) of that disease, excepting that its severity is often greater, and its duration shorter. Indeed, this is but a variety of marsh fever, owing its continued and otherwise modified characters to high temperature and other concurrent circumstances.

397. As this fever varies from the ardent seasoning, to the distinctly remittent type, with the intensity and concurrence of the causes producing it; and as it may occur contemporaneously with the pure climate fever, and with the more inflammatory forms of remittent fever, as frequently observed in the West Indies and Mediterranean during the hot months, particularly among soldiers and sailors; so it is often difficult to distinguish between them. The chief circumstances, however, which will fix the attention of the practitioner, are—the manner of invasion; the distinctness, obscurity, or absence of remissions; the degree of excitement characterising the early period, especially as expressed upon the vascular system;

the kind of excitement, particularly in respect of sthenic or asthenic action; and the state of the circulating fluid, and of the secretions and excretions.

398. *c.* From *epidemic or pestilential yellow fever*, this disease is distinguished — by passing into the periodic type in many instances, and by frequently leaving visceral disease behind it; by its attacking the same individual oftener than once, if he have intermediately undergone a change of locality or climate; by the more inflammatory or sthenic character of the period of excitement, and the much less remarkable change in the blood and soft solids from the commencement; by the headach being confined chiefly to the temples; by the yellowness appearing early, and first in the eyes, and being of bilious origin; by much less irritability of the stomach in the advanced stages; and by its longer duration — generally from five to fourteen days. In pestilential yellow fever, the yellowness of the skin is not frequent, and is of a pale lemon colour; the face has a putrid, bloated, or livid hue; its duration is from one to five days; it never passes into the periodic type, nor leaves visceral disease behind it; fatal cases always being attended by the black vomit at their close. Moreover, remittent, inflammatory, and bilious fevers are never infectious, unless under peculiarly favourable circumstances, when the latter may assume this character; but epidemic yellow fever is remarkably infectious; and whilst these are generally benefited by vascular depletions during the period of excitement, the epidemic malady requires a different method of cure.

399. *iv.* The *PROGNOSIS* depends upon the intensity and concurrence of the exciting causes; upon the severity of the attack; upon the treatment adopted at the commencement; upon the state of vascular reaction; and upon the complications that may arise. — *a.* It may be favourable, if the attack be mild or simple, the skin moist, the vomiting moderate, and the matters ejected consist chiefly of mucous or ingesta; if the tongue become moist, the bowels loose, and the stools bilious; if the nervous and vital powers be not much reduced; and if the yellow suffusion be slight or slow in its progress. — *b.* An *unfavourable* opinion should be formed, if any of the more dangerous symptoms enumerated above supervene (§ 392.); especially if the skin be either early or deeply yellow, or the sensorial functions early disturbed; if the period of exhaustion be attended by deep redness of the face, dulness of the eyes, much anxiety, or laborious respiration; by a feeble, creeping, or intermitting pulse; by very scanty and dark urine; great pain, tension, or fulness in the epigastrium and hypochondria; difficulty of swallowing; tremors of the tongue or of the extremities; by startings of the tendons; involuntary discharges of fæces, particularly if they be of a black colour; incessant vomiting, especially if the ingesta be dark, or great in proportion to the ingesta; by petechiæ, enlargements of the parotids, and coldness of the extremities.

400. *v.* *CAUSES.* — Gastro-bilious fever is caused chiefly by exhalations from the soil, or from vegetable and animal matter undergoing decomposition, in connection with atmospheric heat; by exposure to the sun; by the night airs or dews, and the influence of cold following such exposures or exces-

sive exertion or high ranges of temperature; by intemperance and errors of diet or of regimen; by excesses in vinous or spirituous liquors; by great exertions following inactivity; by over-eating, or by a sudden transition from a very poor, to a very full or rich diet, as in the case of soldiers and recruits; by anger and other mental emotions; and by the causes already enumerated (§ *b.*). — It most frequently, however, arises from the concurrence of two or more of these causes. The influence of infection in producing it has been doubted; but the experience of Drs. DENMARK and BOYD, in ships and hospitals in the Mediterranean, has demonstrated its occasional origin in the cause — or at least the power infection evinces in producing a severe modification of it.

401. *vi.* *TREATMENT.* — The *indications* are — 1st. To evacuate morbid secretions in the prima via, and restore the suppressed perspiration, in the stages of premonition and invasion; — 2d. To moderate the vascular reaction attendant upon the period of excitement; — 3d. To obviate determination to a vital organ, and mitigate urgent symptoms; — and, 4th. To support the vital powers in the consequent exhaustion. — The *first* indication is best fulfilled before reaction is developed. At this time an *emetic*, followed by diluents, by the *vapour bath*, or by warm fomentations, *sudorific drinks*, and by warm emollient enemata, will generally restore the suppressed perspiration, and moderate the consequent reaction. — *Bloodletting* is the next important means; but the utmost care should be taken not to resort to it before reaction has commenced, or when exhaustion is about to supervene. Dr. DENMARK has insisted upon this, and my experience fully confirms the propriety of the advice. I have seen this fever most remarkably exasperated, and almost fatal syncope occasioned, by the abstraction of even two or three ounces of blood during the stage of invasion, before vascular excitement was developed. When this pathological state has supervened, depletions should be energetically and early practised, but with due regard to the state of the pulse, and to the complications and other circumstances of the case; and they ought to be aided by cold applications to the head and purgatives. A full dose (from 10 to 20 grains) of calomel may be given immediately upon the first bloodletting, and afterwards the tartrate or citrate of soda or of potash may be taken at short intervals, in the state of effervescence, with an excess of the alkali. — As long as vascular excitement is energetic, antiphlogistic remedies should be employed, as recommended above; and, in addition to these now mentioned, there are none more deserving of adoption, than small and frequent doses of the nitrate of potash and hydro-chlorate of ammonia. Cold affusions, and cold sponging of the surface, are also useful auxiliaries. When internal viscera are oppressed, and reaction is not free and open, the tepid bath, or tepid effusions, will be serviceable.

402. The *second* indication is to be fulfilled by local depletions in the first instance, followed by rubefacients, blisters, and the other means detailed when treating of the remittent form of bilious fevers (see § 251, 252—258.). — The *exhaustion* in the latter period requires the same treatment as already advised for this state in the

severer forms of remittent and inflammatory fevers (see § 253, 256, 257.).

403. The *mercurial plan* of cure in this fever has been very strenuously insisted upon by CHISHOLM, DENMARK, J. JOHNSON, BOYLE, BOYD, and various other recent writers. They advise *calomel* to be given after copious vascular depletions, with the intention of affecting the system, and in various forms of combination—with James's powder or other antimonial preparations, in frequent doses, or in larger quantities with opium. And they direct the mercurial unguents to be used externally at the same time. I have prescribed mercurials with the same intention, to the utmost extent, and in all these forms in the more concentrated varieties of this fever in hot climates; but I have not satisfied myself that they have been actually beneficial to the extent supposed, even in the cases which have recovered during or after their exhibition. I would, therefore, prefer to use it in the manner I have advised in the severer forms of remittent (§ 250, *et seq.*).

404. The propriety of having recourse to *emetics* in this fever has been much questioned by writers, and especially by those of the school of M. BROUSSAIS. They are, in my opinion, quite inadmissible after excitement has commenced. They should be given only in the premonitory and invading stages, as above stated (§ 401.), but unfortunately the disease seldom comes under treatment until these have been superseded by reaction; and they ought to be aided, in these periods, by the means mentioned (§ 401.) in connection with them. They are contra-indicated even thus early, if great pain be felt at the epigastrium, with distension and tenderness; and if full and free vomiting have already taken place.

405. The *saline treatment*, so remarkably extolled by Dr. STEVENS, in the latter stages of this and other severe fevers, does not appear to have been employed to an extent which will warrant an opinion as to its effects. And, although several years have elapsed since it was so strongly recommended by this writer, for these diseases, I cannot find that any additional evidence of its efficacy has been adduced. It surely becomes this physician to furnish further proofs of its success, and it is morally imperative upon practitioners in warm climates to give it a proper trial.—It is unnecessary to offer further remarks on the treatment of this species of fever, as the observations already made in respect of the management of remittent and inflammatory fever will in a great measure apply to it; and the more so, as the severe states of these diseases, as well as of this, although commencing differently and evincing certain modifications in their early course, generally present very similar features in their advanced stages, or when they assume dangerous complications, and pass into exhaustion of vital power.

Conwell*, On the Funct. and Struct. Changes of the Liver, and on Hepatic Disease in India, &c. 8vo. Lond. 1835, *passim*.—See also the REFERENCES TO REMITTENT AND INFLAMMATORY FEVERS, and likewise to PESTILENTIAL YELLOW FEVER, as this disease has been very frequently confounded with them, owing chiefly to the circumstance of *yellowness* of the skin being one of its chief characteristics; indeed, this symptom is more generally observed in it than in the other fevers just mentioned. The term *yellow fever* ought to be entirely discarded; as, *yellowness* being improperly viewed as a pathognomonic symptom of one kind of fever, all others, in which it is a contingent phenomenon, although not more frequently met with in one than in another, have been confounded with that fever. As respects *intermittents*, their periodicity and exacerbations sufficiently distinguish them, even although *yellowness* or signs of malignancy should arise in their advanced course. Besides, *yellowness* is a very indefinite symptom,—it not only is of various shades, but also arises from very different causes;—it is lurid or tawny in one case, brownish or mahogany-like in another, greenish in a third, orange-colour in a fourth, of a lemon tint in a fifth; and it is, moreover, either partially or generally diffused, or even mixed with different colours, as with greenish, livid, purplish, violet, or reddish blotches. And it may proceed either from the passage of the colouring parts of the bile into the circulation, or from incipient dissolution of the blood, with loss of the vital tone of the capillaries. When it arises from the former source, especial disorder of the biliary secretion is presupposed; in the latter, predominant affection of the circulating fluids and of the vascular system. It would be preferable, therefore, to adhere to the denominations *inflammatory, bilio-gastric, and pestilential*, as respects those species of fever which most frequently present the symptom in question as the result of these causes.

Those who have not seen the fevers incidental to inter-tropical countries, more especially to the West Indies, Africa, the Mediterranean, and the East, may consider the distinctions made above not to exist in nature, and that remittent, bilious, continued, inflammatory, and pestilential fevers are merely modifications and grades of each other. They may even doubt the utility of the details into which I have entered, particularly as regards inflammatory and bilio-gastric fevers; for they will scarcely observe a case of either in temperate countries, particularly in the severe forms met with in warm climates, unless in very hot seasons, and in peculiar circumstances. But in those parts of the world to which I have

just referred, and in others adjoining them, to which medical men may proceed to serve, it will be found that the unacclimated, according to their constitutions, will be affected by inflammatory fevers of various grades of severity, in healthy localities and in hot and dry seasons—with bilio-gastric and remittent fevers, of various forms, in miasmatic situations and sickly seasons,—whilst the acclimated shall escape the first of these maladies, in the former of these circumstances, and the second in the latter, or, if attacked, they shall experience only remittents or intermittents. The pestilential yellow fever makes no such distinctions. As already stated, and as will be hereafter shown, its spread is limited only by a low range of temperature, by a previous attack, and by circumstances that circumscribe its infection. Whilst the former fevers are met with in all warm climates, and occur either sporadically or endemically in them, and are not infectious, this last appears only on the intertropical shores of the Atlantic, or parts adjacent, during hot seasons, rages for a time, and then disappears. Thus, it occurs after long intervals, prevails sometimes for years, and then takes its departure, as will be shown in another place. When we consider the very different constitutions—original and acquired—of those who inhabit European colonies within the tropics,—when we review the appearances of the new comer, of the old resident, of the creole, of the mulatto of various grades, and of the negro, and take into account the modes of living, the exposures, and the various other circumstances connected with each class, and further connect all these with variety of situation, season, and temperature,—we cannot be surprised at the very different forms which fever assumes among them.

406. CHARACT.—*Slight febrile reaction following chills, with mucous evacuations, and pains in the back and limbs, and often with slight remissions.*

407. i. SYMPTOMS.—Some of the older writers confounded mucous fever with *influenza*, with *catarrhal fevers*, and even with *bronchitis*. But more recent observers have, with greater propriety, confined their description of it to that form of general affection, which is characterised by slight febrile excitement and nervous depression, with predominant disorder of the digestive mucous surface, of a sub-acute form, accompanied with mucous or slimy evacuations—admitting, however, the occasional complication of bronchial irritation with it.

408. This fever is *preceded* by general uneasiness, by a sense of heaviness; or pains in the limbs, loss of appetite, disturbed sleep, acid or acrid eructations, and cold or chilliness, which is first felt in the lower extremities. To these succeed, marked dislike of food, slight thirst, nausea, sometimes with vomiting of a whitish, transparent, and viscid fluid of a nidorous or acid taste; a sense of weight at the epigastrium, with fulness; flatulent and colicky pains, with slight tenderness in the abdomen, and relaxed bowels. The tongue is usually moist, white, and covered by a mucous coating, with a sickly or unpleasant taste of the mouth; aphthous exudations are occasionally observed on the fauces and lips; the saliva is sometimes abundant; and the breath is foetid and heavy. The evacuations are mucous, more frequent than natural, sometimes tinged with blood, voided with slight tenesmus, and, in children, often with *prolapsus ani*. In rarer instances, costiveness, or an irregular state of bowels is observed;—mucous diarrhoea and costiveness alternating; and, occasionally, worms are voided. The urine is either scanty or natural at first, of a citrine tint, and sometimes passed with pain; it depo-

sits a mucous sediment of a greyish or brick colour at an advanced stage. The temperature of the surface is not much increased, unless during the evening exacerbations; and, towards the acme and decline, a gentle perspiration breaks out, especially in the morning and during sleep. A slight eruption often occurs during the night, but generally disappears in the morning. The pulse is feeble and small, but seldom much accelerated, unless in the evening and night. The patient complains of a sense of weight or of pain in the scapula and occiput; with vertigo upon sitting up; of confusion of ideas, and somnolency, without the ability to sleep; of depression, sadness, and restlessness; of pains and soreness in the hypochondria, in all the limbs, and in the joints; and occasionally of cough, noise in the ears, and deafness.

409. ii. The **DIAGNOSIS** rests upon the circumstances connected with the origin of the disease; on the appearance of the evacuations; on the colicky pains in the bowels; on the softness, the very slight acceleration or slowness of the pulse; on the little increase of the temperature, and the humidity of the skin; on the slight degree of thirst; and on the very moderate or sub-acute character of all the febrile phenomena. In its slighter forms, the complaint is commonly described as fever from cold, or as a cold in the bowels and limbs. In some cases, it presents either a dysenteric or a rheumatic character; and is with difficulty distinguished from dysentery, or from rheumatism in other instances, unless the history of the disease, and the state of the bowels and of the evacuations, be closely observed. It may even pass into either of these affections, or into others about to be noticed.

410. iii. DURATION, TERMINATION AND PROGNOSIS. *A.*—The *Duration* of this fever varies from two to five or six weeks. It often presents slight remissions, indicated chiefly by the pulse and skin. The more manifest the remissions, the longer is its duration, which may be extended even beyond the latter period.—*Relapses* are very common during convalescence; and are caused chiefly by errors of diet or of regimen, by premature exposure to atmospheric vicissitudes, or to cold and moisture, or to paludal exhalations. The relapse may assume either the same or aggravated features, or a purely remittent or intermittent type.

411. B. Mucous fever *terminates*—1st, In a return to health, which most commonly takes place; and is frequently preceded either by vomiting, or by a moderate diarrhoea, or by an aphthous eruption on the lips, or by a miliary eruption on the skin, by a general sweat, by the urine becoming copious and depositing a sediment, or by a spontaneous salivation;—2dly, In the adynamic state of fever, with predominant affection of the intestines, and of the brain, or of its membranes;—3dly, In a purely remittent or intermittent type, or in dysentery, particularly in marshy localities; and, in such cases, sub-acute or chronic disease of one or more of the viscera in the abdomen, with or without dropsy, may supervene;—4thly, In unequivocal symptoms of rheumatism, or of peripneumonia;—5thly, In death, after severe, inflammatory affection of the intestinal mucous surface, attended by obstinate diarrhoea; or after excessive nervous exhaustion, or after

obscure affection of the brain, or of its meninges, or of the respiratory organs.—The prognosis is generally favourable, unless any of the more severe changes just mentioned present themselves. This fever seldom terminates fatally when early and judiciously treated.

412. C. *On dissection*, the principal lesions are found—1st, In the *intestinal canal*, which is usually greatly distended by a fœtid gas; its mucous surface presenting inflammatory appearances, consisting of vascular injection, thickening, softening, various alterations of colour, ulcerations, and even gangrene;—2dly, In the *peritoneal covering* of the intestines, which is either partially inflamed or altered in colour, the abdominal cavity sometimes containing serum;—3dly, In the *mesentery*, which often presents lesions similar to those of the peritoneum, the mesenteric glands being enlarged, inflamed, or changed in colour;—4thly, In the *liver and spleen*, which are variously altered in different cases, but most frequently congested, enlarged, or granulated; the spleen being generally softened, friable, enlarged—more rarely small and hard;—5thly, In the *lungs*, which are congested or injected, hepatized, tuberculated, the bronchi being loaded with mucus and the bronchial glands enlarged;—6thly, In the *pericardium*, which sometimes contains a turbid or sanguinolent serum; the substance of the heart being flabby or soft.—Morbid appearances, consisting chiefly of congestion and effusion of serum between the membranes or in the ventricles, are occasionally observed in the brain. In every instance, the *digestive mucous follicles* have been found enlarged, inflamed in various degrees, and ulcerated; presenting the various lesions, affecting these follicles, described in the article DIGESTIVE CANAL (§ 36.); the cæcum, large bowels, and small intestines, being the parts chiefly diseased.

413. iv. CAUSES.—This variety approaches bilio-gastric fever on the one hand, and the enteric form of synochoid fever, on the other. It may occur either sporadically, endemically, or epidemically; and, in either case, it may arise from, or pass into, fever of a periodic type. It may even run into dysentery; and from the severity of the pains in the limbs attending it, may closely resemble an attack of rheumatism. Its characters, both constant and contingent, result from the various circumstances both intrinsic and extrinsic to the patient, concurring to cause it. These are chiefly—*a.* The epochs of childhood and old age; the female sex; the lymphatic, leucophlegmatic, and nervous temperaments; prolonged watchings; excessive fatigue or indolence; languid, weak, delicate, and pale states of frame; chlorosis, intestinal worms, or a cachectic habit of body; the debility caused by previous disease, as by agues, mesenteric obstructions, or by excessive venereal indulgences.—*b.* Living in low, humid, cold, and marshy places; privation of light and of the sun's rays; the autumnal season, or prolonged wet and cold weather; want of cleanliness; the use of indigestible vegetables, of unripe fruit, of tainted animal food, or of unwholesome fish, particularly shellfish; of stagnant, marshy, or impure water; the privation of accustomed stimuli; the abuse of emetics or of purgatives; insufficient nourishment, &c. The most common of these are cold and humidity, unhealthy localities, and unwholesome

ingesta. This fever is *endemic* in the situations just specified; and it has occasionally appeared epidemically during autumn and winter, particularly after much wet.

414. v. TREATMENT.—SELLE, STOLL, and J. P. FRANK, looked upon the character of the stools as the consequence of accumulations of mucus in the digestive canal, and have prescribed emetics and purgatives in order to evacuate them. BAGLIVI more judiciously directed vascular depletions, emollients, and mild purgatives. PINEL first evacuated the stomach by means of ipecacuanha; and either continued this substance afterwards, in weak aromatic infusions, or gave rhubarb with the tartare of potash, or with the hydrochlorate of ammonia. He occasionally directed three or four grains of the extract of jalap in an emulsion, as recommended by ROEDERER and WAGLER. BROUSSAIS and his disciples, viewing this fever as a form of primary *gastro-enteritis* developed under the influence of cold, humidity, and bad diet, in persons whose mucous surfaces are predisposed to inordinate secretion, and who are liable to sympathetic affections of the limbs, head, &c., advise a treatment founded on these views. They believe that collections of mucus in the *prima via* are not the cause of the constitutional disturbance, but are, equally with such disturbance, produced by the inflammatory irritation of the mucous surface. There can be no doubt of the frequent origin of the morbid secretion in this state, but that it always, or solely, originates in it, is questionable. Although inflammation, or rather vascular injection, of the mucous membranes is one of the constituents of the morbid condition, there are obviously others which modify it, or give it a more or less specific character. Besides, the follicles are more affected than the mucous membranes themselves; and however prominent the affection of these parts may be, the organic nervous system is manifestly that which is primarily impressed by the causes, and which continues longest and most universally to evince disorder.

415. *a.* The first intention is to remove the exciting causes; and, if the disease comes under treatment sufficiently early, to endeavour to arrest its progress, or to shorten its duration, by the exhibition of an emetic of ipecacuanha, by the vapour bath, by hot fomentations, and by warm emollient injections.—*b.* The second indication is to reduce vascular action, if the disease be fully developed, or the patient plethoric or robust, and if febrile excitement be considerable, by general or local bloodletting, in moderate quantity, by refrigerants, by the tepid bath, and by low regimen.—*c.* The third intention is to determine the circulation to the surface, and derive from the mucous surfaces by means of DOVER'S powder, or by ipecacuanha, nitre and opium, or other diaphoretics; by the warm bath; and by blisters, sinapisms, or warm terebinthinate epithems applied over the abdomen.—*d.* The fourth object is to soothe intestinal irritation and to correct the secretions, by emollients and demulcents given by the mouth or by injection; and by small doses of blue pill or hydrargyrum cum creta and camphor, with DOVER'S powder.—*e.* The fifth is to evacuate morbid matters from the intestines, and to prevent their collection, by the occasional exhibition of mild purgatives and

laxative enemata. — *f. Sixthly*, to alleviate urgent symptoms, or determinations to particular organs — as to the head, the lungs, or liver — by local depletions, external derivatives, rubefacients; &c. — *g. And, seventhly*, to support the powers of life in the latter period by gentle tonics, light nourishment, and by cinchona or the sulphate of quinine, especially when the disease presents remissions, or is disposed to pass into the periodic type, or into rheumatism, and particularly in humid, marshy, and unwholesome situations. I have found the following aperient very serviceable in this form of fever, when the bowels required to be gently but freely evacuated. Others, however, in the APPENDIX (F, 266. 430. 827.), will be equally useful.

XX. FEVER, SWEATING. — SYN. *Miliaris Sudatoria*, *Sudor Miliaris*, *Miliaria* (from *milium*, a millet seed), *Sudor*, *Sudor Anglicus*, *Sudor Picardius*, *Febris Sudatoria*, *F. Helodes Sudatoria*, *Sudatio Febris Helodes*, *F. Miliaris*, *F. Vesicularis*, *Purpura alba*, Auct. var.; *Miliaris*, *Sauvages* and *Sagar*; *Febris Purpurata*, *F. Hoffmann*; *La Suette*, *La Suette Miliare*, *La Suette Epidémique*, *Fièvre Miliare*, *Pujol*, *Gastellier*, *Menière*, &c.; *Der Friesel*, Germ.; *Miliary Fever*, *Sweating Miliaria*, *Sweating Sickness*.

416. DEFIN. — *After lassitude and general uneasiness, a sudden attack of febrile disorder, with most profuse and continued sweat, frequently followed by an eruption of miliary vesicles, the disease occurring epidemically and being infectious.*

417. I have preferred the name *sweating fever* to that of *miliary fever*, as sweating is the constant and characteristic phenomenon of the disease, and is present in the mild as well as in the most malignant cases; whereas the miliary eruption is sometimes wanting in both. This malady should not be confounded with the febrile affections of lying-in women, attended by sudamina, that have improperly been denominated miliary fever, from the character of the eruption sometimes occurring as a symptom of them, during hot seasons and a too heated regimen. This is a specific fever, seldom observed in modern times, in this country, although frequently prevailing epidemically in many parts of Continental Europe.

418. i. HISTORY. — The epidemics which have been variously denominated, as stated in the *Synonymes*, have manifestly been modifications of the same disease, caused by the varying circumstances connected with its appearance. — The epidemic sweating sickness, which appeared between 1485 and 1523, and which ravaged England in these and several intermediate years, was evidently, as supposed by MM. OZANAM and RAYER, a most violent form of this malady, in which the sweat was the most prominent symptom, and the progress most rapid and acute. But many cases noticed by BOYER and others, in recent epidemics, were similarly characterised. — (a) The epidemics observed in France by RIVERIUS, during 1618; in Germany by WELSCH and LANGIUS in 1652; in Francfort in 1653; in Augsburg in 1660; in Bavaria in 1666; in Holland by GRUNWAL, in 1666; in Hamburg in 1675; in London and in Edinburgh, towards the end of the seventeenth century, by HAMILTON and SIRBALD; in Saxony in 1694; in Hungary in 1697; in Plymouth by HUXHAM, in 1738; in Normandy by LE PECQDE-LA-CLOTURE, in 1740; near Mantes by QUESNEY, in 1750; in Navarre by AUGUSTINIS, in 1755; in Bayeux from 1769 to 1776; in Piedmont by ALLIANT, in 1758, and by DAMILONIO in 1782; and in Toulouse and the vicinity by GALLET DU PLESSIS, in 1781; were essentially the same disease. In all these, the fever was ushered in by chills, horripilations, and other premonitory and invading symptoms, which were soon followed by pains in the head, loins, and limbs; by nausea, flushing, profuse sweat, dyspnœa, and, about the third day, by a miliary eruption. Numerous other epidemics that have presented this form of eruption as a prominent symptom, have been described by writers, who observed them during the two last centuries. But in these it was apparently caused, either by a too heating treatment and regimen, or by the neglect of evacuations during the early stage of the disease; and it was not always connected with excessive sweat. It was, indeed, in most cases merely a symptomatic eruption appearing at an advanced period, in a similar manner to petechiæ, &c., with which it was even sometimes associated. In the epidemics, however, which I have above enumerated, the eruption was not a consequence of neglected evacuations, nor of a heating regimen, for the treatment was generally depletory and cooling, and it occurred earlier in the disease, although always preceded by profuse sweat, which was coëtantaneous with the vascular excitement, and always peculiar and offensive. So thick a vapour generally surrounded the sick, arising from the excessive perspiration, that the flame of a candle was obscured by it.

419. (b) The epidemic occurrence of sweating fever in various parts of Picardy was first noticed in 1718. Since that time it has frequently appeared in that province, and in other parts of France; and has more nearly approached, than the epidemics noticed above, the characters of the sweating sickness of the 15th and 16th centuries, in respect of the rapidity of its course, the profuse sweat, and the frequent absence of the miliary eruption. The sweating fever of Picardy appears to have prevailed more or less in various parts of this province and of Flanders, from 1718 till 1747. In this year it appeared in Paris; and

was described by BELLOT, MALOUIN, and BOYER. In various seasons, cases equal in severity to those of the terrible sweating sickness of the 15th century occasionally occurred. These writers observed some that ran their fatal course in fifteen hours, although more generally death did not take place until the third, fourth, fifth, or sixth day, or ever later. When patients passed the seventh day, they generally recovered.—The most robust were the most violently attacked; children and the aged generally escaped. Irruptions of this form of the disease occurred in various parts on the Oise, in 1747; at Beauvais in 1750; in several parts of the north of France in 1753; and in the environs of Amiens in 1758. (MEYZEREI, VANDERMONDE, &c.) The chief peculiarities of these epidemics were a frequent occurrence of hæmorrhages, and of severe and complicated cases, often terminating fatally at the end of one or two days. Robust persons were the most severely attacked in these as in other epidemics. Females often experienced menorrhagia in the course of the disease; and hæmorrhages occurring on the third or fourth day were generally fatal. The sweat was foetid, or putrid, as likewise was the air expired by the patient. Bloodletting was employed at the commencement in the more robust and plethoric; at an advanced stage it was most injurious. Emetics, cooling aperients, acidulated drinks, refrigerants, &c. were also prescribed; and at a later period the preparations of cinchona, the decoction of contrayerva, camphor, &c. These were found the most successful remedies.—The epidemic of Saint Quentin, in 1768 and 1769, was generally ushered in by slight chills, rapidly followed by great heat, thirst, pains, and other symptoms. The treatment just described was most commonly employed. Since then, several other irruptions of this fever have occurred, presenting the phenomena about to be enumerated. That which took place in 1821, and was ably described by M. RAYER, was evidently more asthenic than those above referred to.

420. ii. SYMPTOMS. — Individual cases of this fever are very much modified, even during the same epidemic, by the prominent affection of different organs in different persons. To this circumstance is to be imputed its great diversity, as to severity and character, even in the same family and in similar circumstances. M. RAYER, however, divides it into two forms, the *mild* and the *malignant*; but it is obvious that intermediate grades are equally common; and that most of the malignant or severe cases are rendered such by local complications. — (a) In the *milder* form patients frequently complain of lassitude, loss of appetite, and pains over the eyes. Sometimes they feel the gradual accession of fever, and as if a vapour were extending over their limbs, until it amounts to burning heat, and more generally constriction about the epigastrium, for a very short time before the *hot vapour* is exhaled in the form of sweat from the surface. Occasionally persons have gone to bed apparently well, and have awakened bathed in sweat, which continued till their recovery on death (RAYER). The tongue is covered with a white, foul, or, more rarely, a yellow fur; and the mouth is clammy. There is more or less thirst, no appetite, and the bowels are costive throughout the disease. The urine is scanty. Respiration is oppressed, and the head aches.

The pulse is slightly accelerated, but becomes more frequent at the period of the eruption; and is commonly full and soft. This state continues through the second, third, and fourth days; on which, but commonly on the third, a slight sensation of tingling is felt, followed by a miliary eruption on the skin. The eruption appears first on the neck, and spreads, either rapidly and generally, or slowly and partially, to the breast, sides, trunk, and insides of the thighs, legs, and arms. It may, however, come out suddenly as well as in succession, and be distinct or confluent. The vesicles which constitute it are the size of millet seeds, diaphanous or pearly, and are easily felt by the fingers. They are often intermixed with red papulæ; and more rarely, bullæ appear on some parts of the body. In about two or three days they dry up, and are followed by a desquamation of the cuticle. — The *sweating* is much more constant in its occurrence than the eruption — is always present, is remarkably profuse throughout the disease, especially before the eruption has become general, as it afterwards is somewhat diminished; and is attended by a peculiar odour, which RAYER, SCHAHL, and HESSERT compare to that of rotten straw, and M. MENIÈRE to that of water impregnated with chlorine, or to that of the stools of patients in cholera. LE PECQ-DE-LA-CLOTURE says that it has a rotten-sour smell. The surface is hot, and more or less red. The sweat, rarefied by the heat, forms a cloud around the patient, that is condensed, and falls like fine rain or dew upon the bedclothes. The dyspnœa seems to depend upon congestion of the lungs and large vessels, and is referred chiefly to the præcordia or to the epigastrium. The headach may be suborbital or general: it is dull, heavy, and depressing, and seems not to be altogether the result of vascular determination, or congestion of the brain. In this form, the abdominal regions present nothing particular. The symptoms decline by degrees, and rarely continue longer than fourteen days; they commonly disappear about the eighth or tenth day.

421. (b) The *severe, complicated, or malignant* form is generally sudden in its attack as well as the mild; but lassitude and want of appetite usually precede it for some days. The principal symptoms of invasion are, sometimes chills or horripilations, and commonly vertigo, violent headach, nausea, efforts to vomit, flushed countenance, urgent dyspnœa; pain in the epigastrium, loins, and limbs; anxiety; throbbings of the arteries, and most profuse sweat. Either the cerebral, or the thoracic, or the abdominal symptoms predominate in different cases, and give rise to distinct complications. Where the head is more especially implicated, delirium, coma, and convulsions are often present, and soon terminate life. In these, the patient first complains of vertigo, severe headach, nausea or vomiting, flushed face, injected and starting eyes, epistaxis, throbbing of the carotids and temporal arteries, &c., and soon becomes delirious and comatose. In rarer instances, the *spinal chord* and its membranes are particularly affected, the patient complaining of painful tension in the course of the spine, with tetanic rigidity or spasms of the voluntary muscles. When the *lungs* are chiefly affected, there is often deep-seated pain in the chest, great dyspnœa, a short and quick respir-

ation, the crepitating rattle, or a blowing noise in some of the lobes of the lungs, diminished sonorousness of the chest, a full and frequent pulse, and bloody expectoration or hæmoptysis, indicating inflammation or inflammatory congestion of the respiratory organs. When the *digestive organs* are predominantly diseased, the patient complains of an acute constrictive pain in the epigastrium, with urgent anxiety, frequent sighing, a sense of suffocation, or of weight in the chest, and an unusual pulsation in the region of the stomach. These appear from the commencement, are exacerbated at intervals, and are most severe just before the eruption. In others, the symptoms indicate affection of the bowels, with constipation; and in some, severe pains are felt in the hypogastrium, with scanty, high coloured urine, and difficulty in voiding it. — This violent form of the disease may prove fatal in twenty-four or forty-eight hours, or in three or four days; but it commonly runs its course in from one to two weeks in favourable cases; sometimes, however, extending beyond three weeks. During convalescence, debility is its chief consequence, secondary affections being rare. Those that do occur, are gastro-intestinal disorders, and the eruption of boils.

422. c. The *alterations of structure* have been imperfectly observed. — When a fatal result has been preceded by anxiety, pain, or burning in the epigastrium, the mucous coat of the stomach and duodenum has been found much injected. In the cerebral complication, the brain has been found congested, the membranes injected, and the ventricles filled with serum. In the pulmonary complication, congestion of the lungs, and hepatization of portions of it, have been remarked. Although epidemic visitations of this disease in France have been frequent in modern times, and fatal cases very numerous, yet its pathological anatomy has been very imperfectly investigated. It is evident that death is caused chiefly by the severity of the complications accompanying it.

423. iii. DIAGNOSIS. — The constant, the profuse, and the peculiar sweat attending the disease from the time of its development, not only characterises it, but distinguishes it from all other fevers. The severity of the complications in the intense form, especially at the time of attack, and upon the appearance of the eruption, the character of the eruption, the epidemic prevalence of the malady, and its infectious nature, further serve to distinguish it. The descriptions of the *sweating sickness* by CAIUS, WILLIS, and others prove that it was a more intense form of this disease than has been lately observed. The characteristic symptoms of the former all exist in the latter; and, although the eruption is not mentioned in the sweating sickness, this appears not to have been a general symptom in recent epidemics. M. RAYER states it to have been wanting in a great number of cases, in the epidemic of 1821; and M. MENIÈRE makes a similar remark as to that of 1832.

424. iv. PROGNOSIS. — Sweating fever, as observed in modern times, is a mild disease in its simple form. Predominant affection of any internal organ will render the prognosis unfavourable, according to the severity of such affection. However alarming the symptoms, if they decline

upon the appearance of the eruption, a favourable issue may be anticipated. M. RAYER states that, in 1821, the eruption was independent of irritation of the stomach; that it was confluent without violent previous pain in the epigastrium or nausea; that it did not always succeed the most profuse and incessant sweat; and that it did not invariably appear in cases where the gastro-intestinal disorder was the most remarkable. Death was often sudden — more unexpected than in the common eruptive fevers, — and often followed upon shrivelling of the vesicles. The greatest number of deaths occurred in 1821, between the ages of 23 and 33. The mortality in males was one in thirteen; and among females, one in twenty-eight. In the earlier epidemics observed in Picardy, the mortality was very much greater than this. It was greatest at the beginning and decline of the epidemic; and among bakers, smiths, and farriers: but was variable in different townships. The epidemic of 1832 was in many instances followed by pestilential cholera. The latter malady often followed the decline of, or convalescence from, the former, and even occasionally appeared in its course; the mortality being thereby much increased.

425. v. CAUSES. — The theatre of the epidemic of 1821, was bounded by extensive forests. M. RAYER states, that the disease is endemic in some situations; and that it may occur sporadically where it has prevailed epidemically. It has been observed only between 43° and 60° North latitude. Moist and shady places, excessive heat, and an atmosphere surcharged with electricity, seem to favour its irruption. No age gives immunity from an attack; but adults and females are most obnoxious to it. M. MENIÈRE states, that many of those who had the disease in 1821 were again attacked, and died of it in the epidemic of 1832. When once engendered, it spreads by infection, in the same manner as typhus, scarlatina, and measles. Unhealthy situations, and the poor in the vicinity of the place where it first appeared, suffered in proportion to their proximity, during these two epidemics. M. MENIÈRE remarks that, of the numerous epidemics which have occurred in France, and in other countries, since 1718, to the present time, there is none which shows its origin, either in marsh exhalations, or in unwholesome food.

426. vi. TREATMENT. — Isolation, temporary migration, and avoidance of the affected, are the only preservative means that can be depended upon in this malady. — The *mild states* require but little aid; and it is doubtful if medical treatment will either shorten or alleviate the attack. In the *severer forms*, and where some internal organ is especially affected, appropriate remedies ought to be employed to guard it from danger. If the affection of the head, or of the chest, or of the digestive organs, be slight, *local depletions* will give relief. If the local complication be severe, general *bloodlettings*, with powerful external and internal derivatives, as blisters, sinapisms, purgatives, &c., will be occasionally used with success. But M. RAYER remarks that the cerebral affection, when severe, is often rapidly fatal, notwithstanding the repeated abstraction of blood: and that the nervous phenomena are occasionally independent of actual inflammation. — After the eruption, bloodletting is always injurious; and if

it be resorted to at an earlier stage, and in large quantity, with the view of cutting short the disease, it may have a fatal effect, but it never will produce the desired result. When the eruption disappears suddenly, dry frictions, *urtication*, *sina-pisms*, *blisters*, and rubefacient liniments, ought to be employed to solicit its return. *Sudorifics* may also be employed in this case; but they are seldom useful in other circumstances, as it does not seem advisable to use means to increase the sweat. SCAHL and HESSERT found *cold bathing* and *aspersion* of cold water beneficial at an early stage; and M. RAYER observed the pain at the epigastrium, and spasm of adjoining parts, preceding the eruption, to cease after the application of *cold epithems* to this region. Emollient cataplasms, *fomentations*, and *clysters*, will alleviate abdominal pain, and dysuria; and the general *warm bath*, the *hip bath*, and frictions of the surface, will have a similar effect, and promote convalescence, particularly if the intestinal or the urinary canal be disordered. In the more recent epidemics, *ipecacuanha* and the preparations of *antimony* were given in the first stage, with the view of rendering the subsequent course of the disease more mild; but this practice was found more injurious than beneficial.

427. The above comprises more than all that M. RAYER, the historian of the epidemic of 1821, has advanced respecting the treatment. TESSIER, BOYER, and MENIÈRE, however, state, that full *bloodletting* at the commencement is generally beneficial, and evidently relieves all the urgent symptoms. Indeed, the epistaxis often attending the cerebral affection, the hæmoptysis accompanying the pulmonary congestion, and the character of the gastro-intestinal symptoms, most obviously demand it. They further advise tepid diluents in moderate quantities; gentle anodynes to relieve the insomnia generally complained of; and mild derivatives to favour the eruption, which, when copious, often alleviates the internal affections. M. RAYER says no more of the use of *purgatives* in this disease, than if such means were entirely unknown. The writers who treated the epidemics in the 17th, and earlier part of the last century, employed them freely, and were certainly not less successful in their treatment than he. M. MENIÈRE advises the milder kinds to be exhibited in most cases, and especially when the tongue is loaded. When the pulmonary congestion is urgent, he directs full bloodlettings and external revulsants; but he judiciously advises the effect of the former to be sedulously watched during the operation, as a too careless mode of abstracting blood, or a too large quantity, may produce instant and fatal collapse. There is evidently more of congestion than of inflammation in all the internal complications of this disease; and vital or nervous power is more or less depressed: therefore, although free depletions are often necessary, they should not be confided in alone; but *camphor*, *ammonia*, *serpentina*, &c., ought to be exhibited according to the peculiarities of the case, and conformably with the principles explained in various sections of this article. When the eruption appears, means calculated to suppress it, or even to delay or diminish it, should be avoided. Vascular depletions have been then found injurious, and even speedily fatal; and cold applied to the surface is equally

dangerous: errors of diet and regimen are likewise injurious.

428. *Regimen*.—Patients ought to be deprived of nourishment of every kind, the first four or five days of the disease, or even longer. Diluents of a mild kind, and tepid, should be given in moderate quantity. A little veal or chicken broth may be allowed about the sixth, seventh, or eighth day; and the quantity and consistency of the food gradually increased. Relapses may follow errors in diet, or consecutive gastro-intestinal disorder may be induced by this cause. The regimenal and other means usually required in epidemical maladies, are necessary in this.

XXI. FEVER, SYNCHOID.—*SYN. Synochus*, *Auct. var.*; *Enecia Synochus*, *Good*; *Synochus mitior*, *S. Smith*; *Common Continued Fever*.

429. *DEFIN.*—*Langour*, *lassitude*, and *chills*, followed by *vertigo*, *moderate vascular reaction*, and other febrile symptoms, of a continued type, and regular course.

430. This is the most common form of continued fever in this country. It appears either sporadically or epidemically. In the latter case, it is frequently complicated, or characterised by predominant affection of some particular viscus or part, and thence generally assumes a severer character than in its sporadic form. It often appears in this latter manner from other causes than infection; but, in circumstances favourable to the generation of an infectious effluvia, this may become a superadded or a chief cause, or, indeed, the only cause; but, in this case, the disease which results is some one of the more common forms enumerated under the *typhoid*

species of continued fever. — As, therefore, the causes of *synchoïd*, and of these forms of *typhoid* fever, are often the same — their intensity and concurrence producing the more severe states of disease, as well as giving rise to an infectious miasm — the view which is about to be taken of them with reference to the former species, will very nearly serve also for the latter.

431. *i.* DESCRIPTION. — *Common Continued Fever* occurs in a simple and complicated form, presenting various grades of severity; the severe and complicated states passing into, or becoming identified with varieties of the adynamic species. The severe states of common fever have been very generally imputed to its complications with inflammation of internal parts; but, although its complications are necessarily severe, yet it may be equally so without any evidence of local or predominant affection. This, however, is seldom the case. — I shall, therefore, first describe the simple form, and afterwards the more usual complications and states of severity.

432. *A. Simple Continued Fever* — *Simple Fever*; *Mild Synochus*; *Synochus mitior* — is usually preceded by the symptoms described above, as constituting — *a.* The *precursory stage* (§ 34.), especially by *lassitude*, and a general feeling of uneasy debility and mental languor. The countenance is pale; the features sharpened, dejected, or anxious; and the pulse weak and small. — *b.* After an indefinite period, varying from two or three, to several days, irregular chills, rigors or shivering, commonly alternating with transient flushings or feelings of heat, are experienced, with the symptoms characteristic of the *period of invasion* (§ 35.). This stage is seldom attended by any actual coldness of the surface, particularly after it has continued a short time; the chilliness being accompanied by increased heat, constriction, and dryness of the skin. — *c.* With the disappearance of the chills, the period of *reaction* or of *excitement* (§ 36.), and all the phenomena associated with it, supervene. The vertigo, pains of the head, back, and limbs, and restlessness, usually present in the preceding stage, are increased in this. The patient complains of mental confusion and inability; of general uneasiness and restlessness; the countenance becomes full and flushed; the tongue white, foul, loaded, or furred; the heat of surface generally rises above 100°, and the pulse and respiration are fuller, stronger, and more frequent than natural; the pulse being commonly from 90 to 100 or 105 beats in a minute. The fever is now developed, and proceeds, as described above (§ 36.), usually for several days, — its duration varying from two, three, or four, days to as many weeks, until it either subsides in consequence of the treatment adopted, or passes off by means of some critical evacuation (*the period of crisis*), which most frequently occurs on one of the critical days, from the 3d to the 21st day from the time of invasion, or that in which chills or rigors were first felt. The stages of *decline* and *convalescence* commonly advance in the manner stated above (§ 41, 42.).

433. This mild form of fever generally *terminates* favourably, even when left to nature; but it may become complicated in its course, or pass into a state of dangerous, or even fatal, exhaustion towards the end of the second week, particularly in weak, aged, and exhausted persons.

The return of the healthy functions is indicated — *a.* by the subsidence of the prominent morbid actions; — *b.* by the appearance of critical evacuations; — *c.* by a quiet and prolonged sleep, out of which the patient awakens refreshed, and partially restored; — and, *d.* by the other phenomena already enumerated (§ 41.), as indicative of a gradual decline of the disease. The transition to a severer form of fever is commonly owing to the occurrence of a predominant affection of the respiratory surfaces, or to the change induced in the circulating and secreted fluids, or to the affection of the digestive mucous surface, or to the circulation within the head.

434. *B. Severe or Complicated Synchoïd Fever* — *Synochus gravior*; *Severe Synochus* — occurs from the same causes that produce the milder disease, either acting with greater intensity, or aided by additional circumstances. — The several stages may present a more severe affection of all the functions than has been now described, without any very predominant lesion of a particular organ; but much more frequently some important viscus betrays increased disorder, generally of an inflammatory or disorganising kind. Yet this predominant lesion is not altogether identical with inflammation — certainly not with the inflammation primarily affecting healthy persons. It is less acute or intense as respects the symptoms attending it, more asthenic as regards the state of constitutional power, and more diffuse and sub-acute in its character, than common phlegmasia. It partakes of more of the features of the erysipelatous than of those of common or pure inflammation. Even when the local affection is more than usually phlogistic in appearance, still it is most important to recollect, especially as respects the treatment, that it is preceded and attended by a more or less severe constitutional disturbance, by lesion of the various manifestations of life, and by a change of the circulating and secreted fluids, — circumstances arising out of the poisonous influence of the febrile cause, and imparting the peculiar characters to this affection, — changing it from the true phlogistic or sthenic inflammatory condition, and determining, accordingly, the consequent lesions (§ 50.). Instead, therefore, of viewing the complication as the cause of the severity of the fever, we should rather consider the intensity of the morbid impression made by the febrile poison, and the resulting consequences, as the principal source of severity and of local affection, aided by the predisposed state of constitution, and of the viscus especially affected. — I shall describe the predominant lesions or complications of synchoïd fever, in the order of their usual succession, and of their frequency.

435. *a. Synchoïd fever with predominant affection of the bronchi and lungs.* — This is the most common, and generally the earliest, complication, although it frequently exists only in a slight degree. The bronchial surface is often more or less congested and irritated, and the structure of the lungs sometimes implicated. — This complication is not necessarily severe in proportion to the severity of the fever; but when it is early present, and its symptoms prominent, it necessarily aggravates the fever, and superinduces further complications, by impeding the changes produced in the blood by respiration.

That the respiratory organs, particularly the bronchial lining, should be very frequently affected in fever, may be expected from the nature of the exciting causes, and the channels through which they invade the system, as already explained (§ 100, *et seq.*)—the respiratory surfaces being the parts on which the morbid impression is generally first made on the frame.—In most instances, the predominant disorder of these organs is limited to the bronchial surface; but, in others, the substance of the lungs is also congested; and, in rarer cases, the pleura is at the same time implicated. During particular seasons and epidemics, and in some climates more frequently than in others, this complication is very generally observed. When the bronchial membrane is especially affected, and the symptoms are very obvious early in the disease, it has usually received the name of *Catarrhal Fever*. But the affection of the bronchi, especially when the mucous secretion is not abundant, and still more frequently that of the parenchyma of the lungs, is often nearly concealed by the severity of the cerebral symptoms superinduced by it, or is latent owing to the altered state of the circulating fluids, or masked by some other predominant lesion. This fact, first clearly established by LAENNEC, points out the necessity of having recourse to mediate auscultation, not only in cases presenting the open symptoms of the pulmonary complication, but also in those of considerable severity, and where the sensorium is much disturbed.

436. The *bronchial affection* is generally not very remarkable during the first two or three days; the patient complaining only of a slight oppression or constriction in the chest, with accelerated respiration and occasional sighing. To these succeed fits of dry cough, wheezing, and, subsequently, the expectoration of a dark viscid mucus. There is often no cough; and the bronchial affection is evinced chiefly by the mucous rhonchus heard more or less extensively upon auscultation, by the disordered breathing, and by the matter expectorated. When the mucous rattle is heard extensively, and particularly if it extend to both lungs, great danger should be apprehended; for the changes induced by respiration on the blood being impeded, this fluid becomes vitiated and induces serious disturbance of the brain, and of the excreting organs and surfaces, ultimately passing into structural lesion. If the affection implicate much of the substance and vesicular structure of the lungs, the breathing becomes hurried, oppressed, or laborious, especially after coughing; and the expectoration rounded and streaked with blood. In such cases, the fever is always severe, and attended with much danger, generally in proportion to the extent to which the respiratory surface and lungs are affected. But the danger is not dependent solely upon the pulmonary affection, but also upon the consequences which have been just shown to arise out of it. When, therefore, with the symptoms now mentioned, the edges of the tongue and lips are dark or purplish, and the countenance of a dusky hue, or flushed or suffused with a dark red; when the patient becomes delirious or comatose; the pulse very frequent, soft, and feeble; the abdomen tympanic, or inordinately relaxed; the temperature of the extremities low, or their motions tremulous; and

the tongue loaded with a brown or black coating; consecutive pathological states of great danger, owing to depressed vital power, and to contamination of the fluids, then exist.

437. It not infrequently happens, that a severe bronchial complication attends the early stage of this fever; and that, as soon as the blood is so contaminated, and the cerebral functions are so disturbed, as to obscure sensibility, and lower irritability, the bronchial affection becomes latent, and its more obvious symptoms disappear; the pathological conditions which it induced being now most prominent, and proving the immediate cause of an unfavourable result. If, in such cases, we succeed in removing the morbid condition of the blood, by exciting the nervous energy and the functions of excreting organs, the bronchial affection often returns, with the improvement in the circulating fluids and in the nervous functions; but it also often disappears entirely with the other affection of important organs, particularly when critical evacuations terminate the disease. This return of the bronchial affection with the decline of the other dangerous symptoms, I have remarked in several cases; but it may generally be permanently removed by appropriate means (§ 530.). In the progress of this complication, the expectoration which was at first scanty and frothy or viscid, or altogether wanting, is more copious, of a pale yellow, or yellowish green hue, and gradually diminishes with the decline of the fever. In some instances, it becomes so abundant, as the disease passes its acme, as to favour the resolution of the inflammatory congestion of the bronchi or lungs, and thus to prove a salutary crisis, as remarked by some of the older writers.—When, with dyspnoea and oppression, there are much uneasiness and inability to expand the chest, with a short and quick respiration, active congestion of the parenchyma of the lungs should be suspected; and if, in addition to these, pain be occasioned on coughing, and on full respiration, an inflammatory state, probably extending to the pleura, may be dreaded.—In the last stage, the skin is dusky and cool; the pulse is feeble and hurried, more rarely slow and intermittent; the headach passes into incoherent wandering, or low muttering delirium, or coma, but never into violent delirium. When sensibility is early impaired, this complication may proceed to extensive organic change, without having been suspected during life, owing to the imperfect evolution of the usual signs, and to the circumstances already stated (§ 435.). But if the breathing be attentively observed, it will be always found more or less disordered in these cases; and if auscultation be also resorted to, the local affection will not pass undetected.

438. *b. Synochoid fever with predominant cerebral affection.*—This complication may appear early in fever, or at any period of its course. It may be the only prominent lesion, or it may supervene on either of the other predominant affections.—It may be only occasionally observed, or it may characterise particular epidemics; and it may, moreover, be slight or sub-acute, or remarkably intense, and in all the intermediate degrees.—In the more *slight* or *sub-acute* forms, it constitutes the *Nervous Fever* of some writers; and, in the more *acute* and *intense* grades, the

Phrenitic or *Brain Fever* of others.—The former of these very nearly approach, in their pathological states, the nervous variety of adynamic fever, denominated *Ataxic* by PINEL, *Neuro-sthenic* by HILDENBRAND, and *Typhus mitior* by CULLEN.

439. *a.* Common continued fever, with predominant cerebral affection—the *Neuro-sthenic* of HILDENBRAND—commences, and proceeds for two or three days, as the simple or mild form of the disease. Either then, or at an earlier period, the patient usually complains of pain in some part of the head, most frequently in the temples and forehead, or in the occiput, extending down the neck. The pain is often constant and severe, but it is sometimes slight or entirely wanting; and it is commonly attended by throbbing of the carotids and temporal arteries, and flushings of the countenance. In those cases where no pain is felt, even upon shaking the head, the cerebral affection may not be less urgent and dangerous; but there is always, in those, a very early and remarkable giddiness, either with or without flushing of the face. Occasionally the pain and giddiness alternate, and the latter is always distressing when the former is absent. The expression of the eyes is either heavy and dull, or morbidly brilliant and animated. The conjunctiva is generally loaded, injected, and suffused, in the former case; and brighter and more glistening in the latter. But the eyes are always more or less sensible to light, the eyebrows contracted, and lids half closed upon exposure to it. Hearing and the general sensibility are also more acute. Noises and light invariably increase all the symptoms. The heat of surface is generally above the natural standard, especially over the head; but it is often not augmented on the lower parts of the body. The patient is watchful and restless, and the expression of his countenance indicative of suffering. In the less acute cases, the pulse, the thirst, the appearances of the tongue and of the evacuations, are nearly as in the simple form; and the symptoms generally continue, without alteration, for several days. An important change then occurs. In favourable cases the slumbers, which were short and disturbed, or attended by a slight dreamy delirium, become quiet, profound, and refreshing. In unfavourable cases the pain in the head changes to a dull, lethargic state, with a great diminution of the sensibility, and with increased injection and suffusion of the eyes. Delirium, if it have not already appeared, now comes on, attended by moaning or by incoherent muttering, during short and interrupted slumbers; the tongue is loaded, dark, and dry; and the thirst is diminished. In from one to three days the insensibility passes into coma, unless a favourable alteration takes place; the pulse becomes very quick, and often rises to 120 or upwards; the strength sinks; and the tongue is more dry. To these succeed tremors, rolling of the head on the pillow, tossing of the hands, picking at the bedclothes, and the other dangerous symptoms consequent upon the more acute states of this complication. Even when this unfavourable change has occurred, a stop may be occasionally put to its progress, although it generally pursues its onward course. A more tranquil and protracted sleep; subsidence of the delirium, or of the tremors, or of the frequency

of the pulse; and a cleaner or more moist tongue commencing at its edges, with an improvement in the appearance of the countenance, and in the state of the skin and of the excretions; are the usual indications of an arrest of the dangerous progress of the disease.

440. *β.* In the more acute states the cerebral symptoms are severe, and their progress rapid, in proportion to the intensity of the local complication; the headach or giddiness, the intolerance of light and noise, and the general sensibility, being coordinately excessive. The pain in the back, loins, and limbs is very great; the skin is often intensely hot, and pungent, particularly over the scalp, and is occasionally covered by perspiration, which is rarely copious or general; the eyes are injected and suffused; the breathing is frequent and suspirious; the patient is anxious, uneasy, and remarkably restless: he rolls the head, and is wholly without sleep. The pulse is at first strong, full, or bounding; but generally devoid of the hardness characteristic of primary or pure phrenitis. Sometimes it is oppressed; and, in the most intense states of complication, it is often intermittent, slow, or not much above the natural frequency. Within four or five days, the pain passes into delirium and insensibility. The delirium is sometimes violent, and is then soon followed by tremors and insensibility; and these by subsultus tendinum. The insensibility increases, and passes into a drowsy lethargy; the delirium continuing, but becoming low and muttering. The patient may still become observant, and answer when roused; but coma supervenes occasionally, with rolling of the eyeballs or squinting, dilatation of the pupils, and falling of the eyelids. The tongue is now parched and brown; the gums and teeth are covered by a dark mucous sordes; the evacuations take place unconsciously and involuntarily; the respiration becomes irregular; the pulse either slow, or remarkably rapid and feeble, or intermittent; and life soon terminates.

441. Between these extreme states there is every grade of intensity, the above symptoms being variously modified. In some cases the cerebral affection is very insidious, and more or less slow; in others, open, manifest, and rapid. In the former it may be indicated only by giddiness and sickness or vomiting; the pulse in the carotids, and temperature of the head, not being affected. In a case of this description, which lately occurred in my practice (Mr. H. of Fitzroy Market), all the symptoms subsided instantly upon bloodletting. It may thus exist nevertheless, although in a more protracted form, and present but few of the above symptoms, which, however, are most frequently observed, but not all of them in the same case. The various grades of this complication may be further associated with considerable bronchial affection, or with the disorder of the digestive canal about to be noticed. In such cases the predominant lesion, either in the head, the thorax, or abdomen, frequently obscures the others, until the treatment, by subduing it, renders them more evident, or until some one of them requires additional activity.

442. *c.* *Synochoid fever with predominant affection of the digestive mucous surface.*—The mucous surface of the stomach and intestines is affected more or less in all fevers, in common

with the rest of the organisation. In the simple or mild continued fever, it is generally less disordered than in any other. But in the more severe form it is often prominently deranged, either at the commencement or at a later period.—*a.* The affection of the *mucous surface of the stomach* is sometimes remarkable from the invasion of the disease. In this case, *retchings and vomiting*—symptoms seldom observed in the thoracic and cerebral complications, particularly the former—are always present; and the fever has hence been denominated by many writers, *Mild Gastric Fever*, from its very close resemblance to the species described above (§ 392.). There are also pain and soreness felt in the epigastrium, or in the left hypochondrium, and sometimes also in the right, with tenderness on pressure. The bowels are generally costive; the tongue is red at its sides and point, and loaded with a dirty yellowish fur; the pulse is soft, regular, full, sometimes strong, seldom above 100; and the skin is hot. This state of disease is often followed by cerebral affection, and all the characteristics of that complication; or it passes into the intestinal or enteric form.

443. *β.* The *enteric affection* is sometimes present almost at the commencement of the disease; more frequently it does not appear until a later period; and occasionally it supervenes upon either the cerebral or the gastric complications—aggravating the former, and allaying the latter of these affections.—In most cases, it indicates a severe form of fever, which, at an advanced stage, is further associated with very marked cerebral disturbance. It commonly commences with *looseness*, and with *pain and soreness* in the abdomen, especially on pressure. Pain and tenderness are much less complained of when this complication occurs late in the disease, or when the cerebral symptoms are also very prominent. In cases of the early appearance of the enteric disorder, abdominal pain commonly ceases as the fever advances, particularly if the head become also very much affected, even when the purging and other symptoms are increased. The tenderness, however, generally continues much longer. The tongue is at first unusually red at the sides and point, loaded with a dirty white or greyish fur, and moist. As the fever advances, the redness becomes darker and duller, the surface drier, and the fur browner; and at last dark mucous sordes collect on the teeth and lips. The abdomen is commonly soft and natural, but is sometimes hard or doughy. The pulse is at first full, and soft, ranging from 80 to 100; but usually becoming more frequent at an advanced period. Thirst is also present, unless when the head is much affected, and at the last stage of unfavourable cases. When this complication does not evince any improvement in the course of two or three days, it assumes nearly the same features as characterise the worst cases attended by cephalic affection (§ 437.).

444. When the enteric affection comes on in the course of the cerebral complication, it may pass unheeded, unless the physician is particularly watchful, and expert in detecting it. In these cases, sensibility is so obscured, that pain is seldom felt, even upon firm pressure; and the bowels are occasionally but little disturbed. The tongue, however, is red at its point and edges,

is covered by a dirty fur, and is dry; the pulse is generally about 110, soft, and small. In both these states of enteric disorder, the looseness or diarrhoea is the most frequent symptom. The stools are from three or four to eight or ten in the twenty-four hours; and are at first feculent, fœtid, dark, and thin. They subsequently become, in unfavourable cases, watery and of an ochrey hue,—an appearance imputed by Dr. BRIGT to ulceration in the intestines. But this result is more common in the enteric complication of adynamic than of synchoid fever.

445. *γ.* The *complications* of the common continued fever of this and other temperate climates, are more frequently *associated or mixed*, as Dr. SOUTHWOOD SMITH has very judiciously insisted upon, than met with singly. In these mixed affections, however, one or other usually predominates more or less; although cases sometimes occur in which it is difficult to say which is most prominent; or the predominating disorder of an early stage subsides, and is succeeded or obscured by another. Occasionally, also, other complications besides those above specified appear, even in the same epidemic.—*Sore throat*, or *inflammations of the fauces, pharynx, or œsophagus*, or severe affection of the *liver*, with more or less disorder of the biliary secretion, sometimes accompanies one or other of the prominent affections above described.

446. *ii.* CAUSES.—*A.* Of the *remote causes* of the varieties of continued fevers most frequently observed in this and other temperate climates, those which precede the operation of the more effective causes, which are usually internal as respects the economy, and which, from the circumstance of their disposing the system to the operation of these latter causes, have been usually called the *predisposing*, require first to be noticed. It is often difficult to determine in what the disposition to be affected by these forms of fever consists, and in what manner it is caused. To say, with many, that it arises from an increased susceptibility, does not advance our information one step, and is merely the substitution of one term for another. Close observation of the circumstances connected with the origin of these diseases will show us, that the disposition to become affected with them is not the result of exactly the same circumstances as favour the appearance of ardent fever. A depressed or weak state of vital power, especially as manifested in the nervous systems, but particularly in that of organic life, seems to be one of the most common causes of predisposition. This is proved by the fact, that perfect health, mental activity and energy, confidence in various means of prevention, the moderate use of tonics, &c., enable the body to resist the impression of the exciting causes, particularly infectious and mephitic effluvia; and that fear of the disease, despondency, the depressing feelings and emotions, fatigue, increased sensibility, disorder of the digestive and assimilating functions, &c., are amongst the most common occasions of these causes taking effect.—But, although diminished energy of the powers of life has a marked influence in favouring the operation of the exciting causes, yet something more is required; and this must be referred to a certain constitution of frame which is influenced sometimes in a relative manner only by relative

causes, and at other times only by positive causes, and which often either resists the operation of the usual causes altogether, or yields merely to the combined action of a greater or less number.

447. A much greater predisposition to be affected by continued fevers exists between the ages of fifteen and thirty-five, than at any other period; the forms of fever being generally of a more inflammatory and acute kind between these ages, and in the sanguine, irritable, and plethoric constitutions; whilst persons past the latter of these ages, and those of a lymphatic, leucoplegmatic, or melancholic temperament, are more liable to experience the lower grades of action. Scarcity, famine, and, consequently, insufficient, and unwholesome nourishment, among the lower classes of the community, are the chief causes of the generation and spread of fevers, especially those of a simple, low, and infectious character. Whatever depresses or exhausts the vital and moral energies, exposes the body to the impression of the exciting causes. The circumstances which produce this effect are fully explained in the article DISEASE (§ 21, 23, 27—36.), and in a previous section (§ 64.).

448. The disposition, also, which is generated by certain epidemic constitutions of the atmosphere and season, should not be left out of consideration. A peculiar diathesis seems to be gradually and generally induced by the epidemic influence, whatever that influence may be in respect of its nature; and this diathesis, or change of the vital manifestations of the organisation, rapidly passes into febrile commotion upon the action of one or more of the exciting causes. The change thus effected in the diathesis, and increased by the impression of the exciting causes, may hence be viewed as the proximate cause, or earliest pathological state, of the disease; and to its continuance or non-continuance after the febrile action is fully developed, is often to be imputed the disposition or indisposition to relapse. This is more particularly the case in respect of the fevers caused by exhalations from the soil and from decayed vegetable matters. Infectious miasms — or the effluvia from the bodies of those in fever — suddenly and remarkably increase the morbid diathesis; but when the resulting disease has been undergone, the morbid diathesis is terminated, and a disposition to a return or relapse is altogether or nearly lost. Although epidemic states of the air thus do not favour relapses of infectious fevers, yet they greatly dispose the system to a first attack upon exposure to the exciting causes, when the diathesis has not been changed by a previous attack.

449. *B.* The exciting causes of continued fever are upon the whole much better known than the states of the system which dispose to their operation. They are extremely numerous; for whatever interests the vital energy so as to disturb generally its manifestations, and to occasion a morbid reaction, may be an exciting cause of fever. — It is unnecessary to enumerate even the most influential of them, as they are adduced with sufficient details, in the articles DISEASE (§ 55—63.), ENDEMIC INFLUENCES, INFECTION, and in an early section of this article (§ 65.). The chief causes of this class of fevers are — 1st. Those which proceed (*a*) from the soil; (*b*) from

its productions in a state of decay; and (*c*) from animal matter undergoing decomposition; either of these acting separately, or all of them conjointly; — 2d. Animal miasms — (*a*) from healthy persons or animals crowded together, or confined in imperfectly ventilated situations, and without due regard to cleanliness; (*b*) from persons labouring under diseases of various kinds in confined apartments; and (*c*) from one or more persons affected by the disease which the effluvia propagates; — and, 3d. Changes taking place in one or more of the various functions, and which having reached a certain pitch break out in open fever. Each of these requires a few remarks.

450. *a.* Emanations from the soil or its productions in a state of decay, are most frequently productive of periodic fevers; but they occasionally also give rise to continued fever, especially during certain states of season and temperature, and in plethoric and robust constitutions. What the conditions are, that occasion the continued, in preference to the periodic type, cannot be precisely stated. Extreme ranges of temperature, particularly high grades of it, and humid states of the air, may have considerable influence, as is, indeed, often observed in warm climates, amongst Europeans who have recently removed thither; but, in this and other temperate countries, the continued forms of fever much less frequently proceed from this source alone, than is supposed by some writers. In many places, exhalations from dead animal matter concur with those proper to the soil and its productions in causing fever; and, in this case, the disease assumes a more continued type and a lower grade of action; the circulating and secreted fluids being more remarkably vitiated. There can be no doubt, also, that the particular form and complication of the fever often depend much upon the water in common use, upon the nature of the soil, and upon the exuberance of its products. Water loaded with decaying animal or vegetable matter; rich, clay, deep, low, and absorbent soils, &c.; and the effluvia from putrefying animal matter; are frequently productive, particularly when conjoined, of continued fever, which often assumes a gastric or enteric character.

451. *b.* *Animal miasms* from a number of persons shut up in small space, in ill ventilated and crowded apartments, and in low and humid localities, as in ships of war, transports, jails, camps, besieged towns, workhouses, &c., will, in favourable circumstances, so contaminate the air with animal effluvia as to give rise to fever, presenting characters of severity in proportion to the extent to which the air is vitiated. Instances of this kind are referred to in the articles EPIDEMICS (§ 12, 17, &c.) and INFECTION, and are adduced by PRINGLE, LIND, BLANE, and by most recent writers on Fever. It is unnecessary to offer any remarks upon this, and the other sources of animal miasms, which act as a poison on sound persons, and occasion fevers, or upon infection as a principal cause of the specific forms of the disease, as they are fully illustrated in that article.

452. *c.* That changes may take place spontaneously in one or more of the functions, and proceed to the extent of giving rise to the worst forms of fever, appears to be fully proved. The chief causes of these changes seem to be protracted or excessive mental anxiety and depression

loss of property, disappointment, wounded pride, humiliating occurrences, &c. These causes, however, often concur with the predisposition arising out of disorder of the digestive and assimilating functions, especially when such disorder is connected with colluvies on the *prima via*, and a torpid or loaded state of the biliary organs; and are reinforced by exposure to cold, insufficient nourishment, changes in the usual modes or habits of life, want of sleep, and exhalations from the soil, &c.

453. *C. Determining influences, &c.* — There are numerous causes which, although often insufficient of themselves to produce continued fever, are remarkably influential in giving rise to predominant affection of particular organs, in modifying its form, or increasing its severity. Several of the exciting causes, moreover, have the power not only of occasioning the disease, but also of determining its type, form, and character. This is the case more especially with the effluvium proceeding from an infected person. It is important to attend to these circumstances, more especially such as determine the nature of the complications, &c. of fever, as a due reference to them guides the practitioner to an appropriate plan of cure. — *Epidemic constitutions* are most influential in thus forming the kind and state of fever (see EPIDEMICS). Next to these are season and temperature; climate and situation; famine; the contingencies of war; employments and avocations; habits and modes of living; mental exertions and moral emotions; and previous disorder of some one or more of the internal viscera.

454. *a.* During cold and dry seasons, the more inflammatory, or sthenic, forms of fever, and pulmonary complications, are observed. In high ranges of temperature, and in those conjoined with humidity, the digestive mucous surface and liver are inordinately affected, and the period of increased excitement soon passes into exhaustion, with marked change in the circulating and excreted fluids, and often in the soft solids. — *β.* Climate, according to its temperature and humidity, exerts similar effects. The situation, when elevated very far from the level of the sea, has a similar influence to cold and dry seasons; but when it is low, confined, or near the sea, rivers, or lakes, the disadvantage of humidity, and the contingent evils of marsh exhalations, tend to aggravate the type, or to complicate the disease. The quality of the water has a remarkable influence, both in generating continued fever, and in determining its form; putrid water, or water containing decayed vegetable or animal matter, generally causing fever of an adynamic, gastric, enteric, or mucous character. — *γ.* Employments and avocations may either prevent or favour attacks of fever. Tanners and workmen exposed to the fumes of pitch, tar, chlorine, &c., are rarely affected, even when fever is epidemic. Persons much exposed to the open air, and vicissitudes of weather, are most liable to fever of a sthenic or phlogistic kind, and to the pulmonary and pleuritic complications. — *δ.* Habits and modes of living are very influential and powerful determining causes of fever, even in this climate. The influence which full and rich living, and its opposite, poor and unwholesome living, exert upon the state of the disease, has been sufficiently manifested by the epidemics

which have prevailed at various times in Ireland since the commencement of the present century, according as they appeared in the poor and ill-fed, and as they extended to those in easy circumstances. In the former, fever usually assumes the common continued, or the milder adynamic and typhoid forms, often attended by the pulmonary complication, or with petechiæ, &c., and frequently passing into dysentery, &c.; in the latter class it is either accompanied, at an early stage, with high action, or with congestion, and predominant affection of the head, liver, or stomach. In persons living chiefly upon fish, it generally assumes a low and putrid character. Those who are intemperate, or who have resorted to spirituous liquors on the invasion of the disease, present especial disorder of the brain and digestive mucous surface. — *ε.* Intellectual exertion, mental anxiety, and other inordinate emotions, may both occasion a severe fever, and aggravate its intensity, even when arising from infection; and, in both cases, a cerebral or typhoid complication, of a dangerous kind, is produced. — *ζ.* Previous disorder heightens the severity of the disease, and necessarily determines its predominant features or complications, although sometimes in an indirect manner. Thus, it is common to observe bronchitis previous to, or attending the invasion of, fever, followed by a remarkable affection of the brain and of the mucous membrane of the intestines. In this case, the changes effected by respiration on the blood are imperfect; and, consequently, this fluid becomes morbid, — disordering first the functions and ultimately the structure, of the digestive mucous surface and brain.

XXII. FEVER, TYPHOID.* — SYN. *Adynamic Fever, Asthenic Fever, Febris Asthenica; Febris Contagiosa; Febris Typhoides; Typhus* (from τυφος, stupor, or τυφω, to smoulder); *Fièvre Typhoïde, CHOMEL; Fièvre adynamique, F. nerveur, F. atavique, Fr.; Tifo, Ital.; Der Typhus, Nervenfeber, Germ.; Low Fever, Contagious Fever, Infectious Fever.*

455. DEFIN. — *After lassitude and general malaise, imperfect or suppressed vascular reaction, with depressed vital power, manifested especially in the nervous, vascular, and muscular systems, and giving rise to changes more or less evident in the circulating fluids and soft solids.*

456. This fever cannot be said to differ specifically from that last described, although certain varieties of it present very marked distinctions. Indeed, the severer forms or complications of synchoid fever very closely approach, or run into, certain states of typhoid fever; the chief differences consisting in the more sthenic vascular reaction in the early part of the period of excitement in the former. Even the milder cases of simple continued fever may gradually assume a perfectly typhoid state, in the advanced stage. The distinctions which characterise the following varieties are results of the circumstances already shown (§ 43.) to determine the forms and complications of fevers generally — especially of the constitution and habit of body; of the previous health and condition of vital organs; of the nature, in-

* I use the term *Typhoid* in the same sense as CULLEN and the majority of writers on Fever in this country since his time. It is, in this sense, nearly synonymous with most of the names adduced under it.

tensity, and concurrence of the causes of the prevailing epidemic; of the influences operating after infection or during the early stages, and of the treatment and regimen then adopted.

i. MILD TYPHOID FEVER.—*SYN.* *Simple Typhoid Fever; Nervous Fever; Simple Adynamic Fever; Regular Typhus; Slow Nervous Fever,* Huxham; *Typhus mitior,* Cullen; *Febris nervosa,* Auct.; *Languor Panonicus.*

457. *A.* This form of fever is characterised chiefly by great languor and debility; by giddiness, dulness, and confusion of intellect; by a soft, feeble, and quick pulse; and by loss of muscular power, sleeplessness, and low delirium. It usually commences with similar *premonitory symptoms* (*period of infection,* HARTMANN) to those above described. The patient complains of giddiness, lassitude, uneasiness at the epigastrium, of nausea and loss of appetite, of alternate chills and flushes, and of pain in the back and limbs,—the *period of invasion.* The chills are often prolonged, or recur for two or three days, but seldom amount to rigor. The skin afterwards becomes warm, but seldom very hot—the *period of excitement, of irritation* (NAUMANN), of *reaction* (HARTMANN), of *inflammatory irritation* (GOEDEN); the pulse frequent, full, soft, or weak; the countenance dull, pallid, and shrunk, or, occasionally, transiently flushed; the head heavy, confused, and giddy; the eye heavy and devoid of lustre; and the tongue loaded or covered with a dirty mucus. There are more or less thirst; a desire of cold, acid drink; sometimes pain at the epigastrium, nausea, and vomiting; or an irregular and relaxed state of the bowels; and offensive evacuations. Pain of the head is but little, or not at all, complained of, but that of the back and limbs is felt severely. *Tinnitus aurium* is generally present. Febrile uneasiness is great, the restlessness constant, and the want of sleep continued.—About the third, fourth, or fifth day, the head is more affected, and the mind more confused. The respiration is short and quick; and torpor, or *coma vigil,* is often observed. Occasional flushes occur in some cases, while the extremities are cool. The urine is pale, of a whey colour, or like small beer—occasionally scanty. The bowels are either torpid, or relaxed, or irregular; and deliquium, or faintness, partial sweats, tremors, &c. are complained of, on attempt to sit up. Delirium of a low kind, or consisting of a muttering incoherence, occurs about this time; generally, at first, during the night, but subsequently recurring during the day. The eyes become muddy, afterwards suffused or injected; and the tongue of a darker hue, dry or incrustated.

458. From the 7th to the 9th, 10th, or 11th day, or even later, the delirium degenerates into stupor—the *period of predominant narcotism* of NAUMANN—the *nervous stage* of HILLENBRAND—the *collapse* of CULLEN and HARTMANN; the pulse becomes small, weak, and very quick, or unequal; the heat of the skin natural, or diminished, or irregularly distributed; the hearing dull; and tremor, the supine posture, coma, and unconscious evacuations, are soon afterwards observed. Petechiæ sometimes appear on the trunk, thighs, &c. The tongue becomes brown or black, incrustated and fissured, is protruded with difficulty, and the gums and lips are covered by a dark sordes.—From about the fourteenth day to a much later period, according

to the character of the epidemic, the peculiarities^s of the patient, the severity of the early stages, and the state of internal organs, a favourable change very often occurs in all the symptoms—the *stages of crisis and decline,* or of *recovery,* (HARTMANN)—and is announced by a refreshing sleep, or by a warm and general sweat, or by a gentle diarrhœa; followed by subsidence of delirium, tremor, &c.; by the tongue being moist and clean at its edges, the skin more natural, and the pulse slower; by returning consciousness; and by the improved appearance of the countenance. If these changes do not take place; or if the sweats are cold and clammy on the extremities; or if they, or the diarrhœa, be unattended by amelioration of the symptoms; a *fatal change* should be dreaded, particularly if profound coma and great deafness, subsultus tendinum, or convulsive or spasmodic movements, difficulty or inability to swallow or to articulate, hiccup, involuntary evacuations, retention of urine, tympanitic abdomen, sliding down in bed; very rapid, fluttering, or intermittent pulse; very black tongue; and a quick, jerking, laboured respiration, or other unfavourable symptoms, appear.

459. *B.* The symptoms which *distinguish* this form of fever from the synchoïd are—the greater prostration of strength from the commencement; the mental torpor and confusion of ideas; the long-continued chilliness, generally without rigor or shivering, at its invasion; the moderate increase of temperature afterwards, or its natural grade; the pallid and shrunk countenance, expressive of suffering and debility; the muddy, lack-lustre eye; the torpor, giddiness, and absence of pain in the head, passing into stupor with delirium at an early stage; the quick and small, or the full, open, and soft pulse, even during the period of excitement; the early dryness, and dark appearance, of the tongue; the remarkable factor of the breath, and of the discharges; the supine posture; the dull, dusky, lurid, or dirty hue of the surface; the frequent occurrence of sloughs in the parts pressed upon, or of erysipelas, and occasionally of enlargement and inflammation of glands; and the early appearance of delirium, with tremor, and other symptoms indicating extreme depression of vital power. When any of these phenomena occur in synchoïd fevers, it is always at a far advanced stage; the synchoïd thus merely lapsing into the typhoid form, owing to various contingent influences, or to predominant affections of particular organs.

460. *C.* Such are the usual progress and characteristic phenomena of simple typhus; but it presents slight modifications, with the activity of reaction in the early stage, with the affection of particular organs or of the skin, and with the character of the prevailing epidemic. When the predominant affection is either so evident or so influential, as to modify materially the state of disease, certain varieties result, which have been described by authors as specific or distinct forms of fever, and have been often connected, in too absolute a manner, with the peculiar circumstances in which they were observed, or in which they originated. I shall here notice these varieties, with reference to the circumstances whence their peculiarities seem to proceed, and to the various names imposed upon them from a desire of appearing

original, but with the effect of proving inaccurate or of causing misapprehension and confusion.

461. ii. **COMPLICATED TYPHOID OR LOW NERVOUS FEVER.**—*A. With predominant Affection of the respiratory Organs.*—The bronchial surface is the part chiefly affected, and is rather congested than inflamed. The pleura is rarely attacked; but the substance of the lungs is sometimes implicated; and it then commonly becomes rapidly infiltrated or condensed, a fatal result quickly supervening. This complication is often obscure, or even latent; but it generally admits of detection by auscultation, or by attentive observation alone. The patient sometimes complains of stricture, oppression, or dyspnoea, but very seldom of pain in the chest. The respiration is short and hurried, is attended by the mucous rattle, and with more or less cough. The skin is seldom hot; at a later period it is cool, or even cold, in the extremities, and dusky or lurid; the cheek is tinged with a dark red, and often assumes a livid or purplish hue. The pulse is rapid and weak. The confusion or stupor of an early stage passes quickly into low, incoherent, muttering, and coma. The tongue becomes very dry, black, crusted, and fissured; it cannot be protruded, and articulation is lost. This state may continue for several days, with unconscious evacuations, and all the nervous symptoms prominently marked; at last the patient sinks asphyxied, the changes necessary to life ceasing to take place in the blood sent to the lungs.

462. *B. Nervous or Typhoid Fever with prominent Affection of the digestive mucous Surface*—the *Adynamic Fever* of several French writers; the *Dothinentérie* of M. BRETONNEAU.—Many of the observations made respecting this local affection in synchooid fever (§ 442.), apply to its occurrence in typhoid fevers. It is very commonly observed in large cities, and in circumstances that occasion the use of water containing animal matter in a state of decay; and it commences in a similar manner to the other varieties of typhoid fever. The symptoms that usually attend its progress are—a tumid, tense, hard, or tympanitic state of the abdomen, at an early stage of the fever, frequently without pain or even tenderness on pressure, but with involuntary stools, and unconsciousness of their passage at a later period. The tongue is dry, black, incrustated, and the crust sometimes fissured; but it occasionally is dark red, dry, and devoid of papillæ or fur. The stools are often ochrey, and more frequent than natural. Discharges of blood, in greater or less quantity, sometimes accompany them; but the hæmorrhage, and the changes in the mucous surface occasioning it, may occur without much, or even any, relaxation of the bowels.

463. *C. Typhoid Fever, with prominent Affection of the cerebro-spinal nervous System*—the *Ataxic* of PINEL.—is seldom attended by acute pain in the head. But heaviness, stupor, confusion, and giddiness are felt severely, and very early in the attack. The eyes are injected, suffused, and devoid of lustre. Delirium appears early, and frequently becomes more violent than in mild typhus; the patient attempting to get up, or out of bed. The scalp is warm, or hot, and the extremities are often cool. Insensibility and coma quickly supervene, and are sometimes attended by spasmodic contractions of the muscles

of a limb, or by partial convulsions. Inability to swallow, retention of urine, and loss of speech are occasionally observed. Startings of the tendons, relaxation of the sphincters, and failure of the circulation, occur in the last stage, and usher in a fatal termination. This complication is especially characterised by the early appearance and the severe form of the symptoms depending directly upon the state of the cerebro-spinal nervous system.

464. *D. Typhoid or Nervous Fever with severe Affection of several vital Organs*—*Typhus gravior* of CULLEN and others—is generally characterised by intense disorder of the brain and digestive canal, with more or less evident affection of the bronchial surface; delirium being early, and at first somewhat violent, and soon followed by insensibility, &c. The pulse is quick and weak; the skin is hot, dry, pungent or harsh, in an early part of the stage of reaction, but it generally becomes cool, particularly in the extremities, and often discoloured; respiration is panting or quick; the tongue dry and black; the abdomen tumid, tender, or tympanitic; and the stools are dark, offensive, and passed involuntarily and without consciousness. In this form there is some degree of reaction, expressed most severely in the digestive canal and cerebro-spinal nervous system; but it is characterised by depression of vital power, that is soon increased by the exhaustion consequent upon the reaction induced in this state.

465. The vital organs may, however, be severely affected, although excitement be very slightly, or even not at all, manifested. Such cases constitute the *Congestive Typhus* of some modern writers,—a form of comparatively rare occurrence, unless accompanied with petechiæ, and other symptoms indicating serious changes, not merely of vital action, but also of the fluids and soft solids.—In this variety the depression of vital power is extreme from the commencement, and such as prevents the development, and, in some cases, even the least manifestation, of excitement. The causes of the disease have given vitality a shock beyond its powers of resistance, or of recovery. Muscular power is almost entirely annihilated, and the anxiety at the epigastrium and præcordia is extreme. Respiration is oppressed, and the pulse is quick, sometimes irregular, intermittent, or even slow, and always small, weak, and thready. The countenance and eyes at first have an intoxicated appearance: the former being pallid, occasionally slightly bloated, or livid and dingy; the latter being vacant or suffused, and, afterwards, injected, ecchymosed, half shut, or open. The skin, at an early stage, is warm or harsh; subsequently it is cool, withered, lurid, and, sometimes, studded with petechiæ or vibices; the extremities being cool, or even cold, and dingy, or of a leaden hue. The mind is very much confused at the commencement, and soon passes into a state of incoherence, delirious muttering, and coma. The patient is unable to protrude the tongue, owing to deficient power of the muscles of the organ; and seldom complains of thirst. The abdomen is tumid or inflated; the bowels being relaxed, the stools black and offensive, and, with the urine, passed unconsciously. The progress of the disease is usually rapid, and gene-

rally to a fatal termination; but the *premonitory stage* may be protracted, although severe — the *invasion* being sometimes sudden, and resembling an apoplectic seizure. If the powers of life rally, recovery may take place; but it is tedious, and often attended by various consecutive disorders.

466. *E. Of other Modifications or peculiar States of Typhoid or Low Nervous Fever.* — Various phenomena beside those already described may accompany this fever, according to the combination and intensity of the causes, the previous health of the patient, and the circumstances affecting him subsequently to the operation of the exciting agent. — *a.* When caused by *mental distress, despondency, &c.*, this fever presents certain peculiarities deserving notice. The patient is dejected, indolent, and incapable of exertion. He loses his appetite and strength; he cannot rest at night, or his sleep is disturbed and unrefreshing; and he complains of headach, and of many of the symptoms of a common cold. He is absent, his mind being constantly occupied with the subject of his misery. His countenance assumes an anxious appearance; his healthy looks vanish; and his absence of mind often passes into a state of reverie. After several days, manifest affection of the brain is observed, with characters varying with the age, strength, condition, and habits of the patient. In the robust, plethoric, and in persons addicted to intoxicating liquors, it is sudden and violent in its accession; the headach and despondency quickly passing into delirium of an active and constant kind — the patient calling out, or starting up, and attempting to get out of bed. The pulse is quick, firm, and oppressed or small; sometimes soft or irregular. Muscular power is not so much, nor so early, reduced as in the other states of the disease, but there is continual tactitation. In the debilitated, the aged, or the ill-fed, the cerebral affection is less violent in its attack, and commences more gradually, often attended by red or suffused eyes, or by catarrhal symptoms, or by diarrhœa; by delirium, tremor, great prostration of strength, hurried breathing, weak quick pulse, subsultus tendinum, and, sometimes, with a mottled appearance of the surface. In other respects, the progress of the disease is nearly the same as the more severe cerebral complications already noticed (§ 463.), but it much more frequently terminates unfavourably.

467. *b.* In some cases the fever is complicated with *sore throat*; and this symptom is occasionally so severe and early as to resemble an attack of *cynanche maligna*. Indeed, cases not infrequently occur, which fully indicate that the one disease may pass into the other, under favourable circumstances in respect of predisposition and concurrence of the exciting causes; or, in other words, that in young persons, in those predisposed to sore throat, and in cold and humid states of the air, certain of the exciting causes of typhoid fever will sometimes occasion a malignant or putrid inflammation of the throat, ushered in and attended by this form of fever; or they will, in such or similar circumstances, produce a low fever, in which inflammation of the throat is a contingent complication, and assumes an asthenic or unfavourable character, owing to the depressed state of vital power, and

morbid condition of the circulation, in which it occurs. This complication is observed either as the most prominent local affection, or in conjunction with some other remarkable disorder, especially with the gastric complication. In some instances it is very severe; the pharynx and upper part of the œsophagus being also more or less affected, and deglutition altogether prevented.

468. *c. Paralysis* may occur, especially in the cerebral state of this fever; and, in this case, the use of one side of the body is generally lost. If the patient recover from the fever the functions of the paralysed side are often gradually restored. This complication may take place in those cases which commence with protracted or severe premonitory symptoms, against which the patient struggles, until he falls down from exhaustion; or is *suddenly* seized, as in a case of apoplexy — the fever running its course, as after the usual invasion, with chills, rigors, vomitings, &c. When the disease is developed in this sudden manner, it commonly presents the cerebral character throughout, with delirium, passing into coma, &c. In a case, however, of this kind, the cerebral symptoms were subsequently slight, and the disease mild.* In some of the cerebral cases of this fever, the affection of the mind continues for some days, or even weeks, after the bodily functions are restored. Instances may even occur of permanent insanity being the consequence. But, in all such cases, hopes of recovery should be entertained until some weeks, or even months, have elapsed from the disappearance of the fever.

469. *F. Relapses and Sequelæ.* — *a. Relapses* are not infrequent after the mild forms of typhoid fever; especially when the duration of the disease has been shortened by the treatment, or its course materially altered. They are also much more common in one epidemic than in another. In many instances, particularly when the procession of the morbid phenomena has been interrupted by large depletions, or drastic purgatives, the symptoms become ameliorated for a time, but recur with their previous severity; the recurrence being different from a relapse. — *b.* This fever, especially its gastric and enteric states, may pass, or be converted, into a low or typhoid form of *dysentery* (see that article, § 26, 27.), owing to the influence of the same circumstances that usually cause relapses; especially premature exposure in early convalescence; the use of too much, or of improper, food; the continued operation of the exciting causes; a close, impure, and infectious air; and suppression of the excretions. — *Local affections*, particularly *inflammations*, may also appear during convalescence, arising either from the above causes, or from atmospheric vicissitudes;

* A young lady went some distance to visit an intimate friend, delirious in fever; and having gone into the chamber, she was sensible of a disagreeable odour upon the curtains of the bed being drawn. She soon afterwards complained of slight nausea, of headach, loss of appetite, and general lassitude. These symptoms continued gradually to increase for six days, during which time she kept about. On the morning of the seventh day she suddenly fell down without sense or motion. I saw her in this state soon afterwards, and, viewing the attack as the result of sudden congestion of the brain, and before I had learnt the above particulars, I prescribed a moderate bloodletting, and purgatives. The functions of the brain soon returned, and the fever ran its course in a mild form, and without delirium or prominent affection of any organ.

or from whatever may inordinately affect the nervous and vascular systems. In these cases the inflammation is apt to pursue a severe and rapid course, owing to the unfavourable or debilitated state of constitution in which it occurs. Bronchitis, often associated with affection of the substance of the lungs, and inflammation of the mucous surface of the bowels, sometimes with softening and enlargement, or ulceration, of the mucous follicles, are the most common diseases thus contingent on convalescence. Inflammatory affections of the stomach or liver may also take place. When the mucous surface of the intestines is the seat of consecutive disorder, the bowels generally are more or less relaxed, and the stools are of an ochrey hue, and offensive. In such cases, the follicles are especially affected; are often ulcerated; and, although they will generally heal under judicious treatment, perforation of the intestines and fatal peritonitis may be the result at a period more or less remote from the disappearance of the fever.

470. *G. OF PETECHIE AND EXANTHEMATOUS ERUPTIONS IN TYPHOID FEVERS.*—Nervous or typhoid fevers may occur sporadically or epidemically, without any *petechial* or other eruption; or may be attended by *petechiæ* or *vibices* in their progress, and particularly at an advanced period, or by an *exanthematous eruption* at an earlier stage; or even by both kinds of cutaneous affection, either successively or almost coëtaneously. For many years, or in successive epidemics, or even in a single epidemic, typhoid fever may appear in any one or more of the states just described; or it may assume either of these forms, associated with one or other, or with both, of the affections of the skin just mentioned in a portion of the cases only; or the affection of the skin may be one of the most unvarying and chief characteristics of an epidemic; and, of the cases composing such an epidemic, some may be of the mild, others of the complicated or severe form; some may evince more or less reaction or excitement, others may present depression of the powers of life and congestion, as prominent phenomena throughout. The above description, although applicable more especially to the occurrence of typhoid fever, independently of any marked affection of the skin, yet does not the less apply to the occasional association of the disease with this affection. Those epidemics, in which the changes in the skin are very constant phenomena, sometimes possess other characters, both in the early and in the advanced stages, that require an especial notice. Whilst these changes—both *petechial* and *exanthematous*—have been considered by HILDENBRAND, NAUMANN, FODÉRÉ, PEEBLES, and other experienced writers, as indications of specific kinds of fever, which, in the early stages, may present more or less either of inflammatory excitement or of depression of vital power; they have been viewed, by many authors, merely as occasional occurrences, or as modifications met with only in certain epidemics, and not as characteristics of distinct varieties.

471. In trying to solve this question, the same difficulties present themselves that arise in all attempts to arrange the different varieties and states of fever in such an order as the more constant phenomena may warrant, and as may conduce to appropriate and successful methods

of treatment. If I refer to my own observations in different parts of the Continent, some time after the late war, and in various parts of this country, both before and subsequently, I shall find—1st. That *petechiæ* and *vibices* were either seldom or rarely seen for several years, in some epidemics, excepting in the most severe or malignant cases, or when favoured by a too stimulant treatment, and a too heating regimen during the early stages; and that, at other times, they appeared more frequently in the advanced periods of the lowest forms of fever, and even, although much more rarely, towards the termination of synochoid fever, when antiphlogistic remedies had been neglected in the stage of excitement.—2d. That this change, in some epidemics, was a very common or even general symptom, occurring in mild as well as in severe cases, although presenting very different appearances in each; and that they were sometimes observed early in the low states of fever, particularly when caused by unwholesome and deficient food, by a foul atmosphere, or by infectious miasms.—3d. That they were very frequently connected, especially in the plethoric, in the previously unhealthy, and in persons using much animal food, with evident change of the circulating fluids, with predominant disorder of the digestive organs, with a soft, broad, and open pulse, and with hæmorrhages from the intestines, and a tendency to disorganisation of the mucous surface of the bowels.—4th. That an *exanthematous rash* or eruption was observed in some epidemics, from the third to the eighth day of the fever, was quite distinct from *petechiæ*, generally appeared earlier, and was, in some cases, either associated with, or succeeded by, *petechiæ* or *vibices*, or even both.—5th. That this exanthema was of a reddish colour, varying in deepness, and rarely passing to a dark hue; that it occurred in cases characterised by vascular reaction in the early stage, as well as in those of a very low grade—in the mild, in the complicated, and in the severe; that this eruption was most probably overlooked in many cases where it existed; and that it was very generally confounded with *petechiæ*, owing to its late appearance, or to its colour changing, in a somewhat similar manner to *petechiæ*, with the states of vital power and of the circulating fluids.—6th. That although the difference between both these affections of the skin has been insisted on by HILDENBRAND and NAUMANN, it has been too widely drawn by them, and without due reference to the occasional association of both affections. From these facts, therefore, I am induced to come to the conclusions above stated (§ 470.); and, conformably with the views of the experienced writers just mentioned, to notice more particularly the states of fever in which these changes in the skin are observed, without considering these states as always constituting distinct species.

iii. TYPHOID FEVER, WITH PUTRO-ADYNAMIC CHARACTERS.—*SYN. Putro-Adynamic Fever; Σύνοχος μετα σπηδεόνης, Galen; Synochus Putris, S. cum Putredine, Febris continua Putrida, Rivière; F. continens Putrida, Selle; F. Putrida sanguinea, Vogel; F. colliquativa putrefaciens, Quesnoi; F. Hungarica, F. nervosa-putrida, F. asthenica, F. contagiosa; F. colliquativa essentialis, Borsieri; F. Putrida*

simplex, Richter; *F. character petrido aut septic*, Hildenbrand; *F. Petechialis*, *F. Nosocomialis*, *F. Castrensis*, *F. Purpurata maligna*, *F. Maligna*, *F. Carceraria*, *Pestis Bellica*; *Auct. var.*; *F. Continens maligna*, Huxham; *Das Faulfieber*, *Faulige Fieber*, Germ.; *Fièvre grave*, *F. Maligne*, *F. Putride*, Fr.; *F. Adynamique*, Pinel; *Febbre Putrida*, Ital.; *Morbo Petechiale*, Cerri; *Febbre Petechiale*, Rossi; *Febbre epidemica Petechiale*, Buffa; *Petechial Typhus*, *Camp Fever*, *Jail Fever*, *Putrid Fever*, *Putrid Malignant Fever*, *Spotted Fever*.

I consider this as a variety merely of typhoid fever, its especial characteristic—the appearance of petechiæ and vibices—being contingent upon certain circumstances and causes tending to contaminate the circulating fluids, and to destroy the tonicity and irritability of contractile tissues, and appearing only as the effect of a series of anterior changes. Although petechiæ may occasionally appear in the advanced stages of other fevers, particularly those of the typhoid form, yet in those epidemics which result from famine, war, unwholesome food, and from air loaded with putrid animal and vegetable matter, or with the emanations proceeding from a number of persons shut up in a close atmosphere—causes which are often conjoined—this symptom is very generally, if not constantly, observed, and is only one of the indications of the very serious changes which have taken place, not only in the blood, but also in the soft and irritable structures of the frame. Infection, either directly or by fomites, is, however, the chief cause, although cold, humidity, fear of the disease, and the other agents just noticed, may either generate the fever *de novo*, or predispose the system to infection, or aid its operation after exposure to it. Although certain epidemics evince a putrid or septic character at an early period, and thereby justify the appellation generally given to them; yet this character is seldom primary, or otherwise than the consequence of suppression or exhaustion of vital power, the fever commencing in some one of the forms already described. Indeed, there is no variety of fever that may not evince a septic or putrid state—1st, from the vital depression produced by the exciting cause; 2dly, from exhaustion consequent upon vascular reaction; 3dly, from the passage of contaminating matters into the blood; and 4thly, from these states conjoined. Hence, when the causes are of a contaminating kind, and the influences continuing to operate after infection have a similar tendency, putrid or malignant symptoms will arise, whether the fever be synochoid, nervous, typhoid, or gastric, in its early periods. These fevers are the most prone to the septic character; but others, as remittent, inflammatory, and bilious fevers, may also assume it. This particular character may, or may not, be developed, or may appear at a later or earlier period, owing to the nature and diversity of the causes; to the condition of the internal functions and of the circulating fluids at the time of attack; to the rigidity or tone, or to the laxity of the softer solids; to the violence or absence of vascular reaction; and to the early treatment and regimen.

473. *A. Petechial*, or putro-*adynamic* fever generally commences with the premonitory and invading symptoms usually observed in other fevers

of a low grade. When an epidemic presents changes of a septic or putrid nature, as predominant features, the early stages of the fever vary most remarkably according to the intensity of the causes, and the state of the patient. The period which elapses from infection till the manifestation of the disease ranges from a few hours to five or six weeks. It is commonly some days, but sufficient evidence has been furnished, in the Irish and other epidemics, that the longest of these periods may occur. During the time the disease thus takes to form, the usual *premonitory* symptoms are observed, and increase until chills, horripilations, or rigors are felt. In some instances the disease commences insidiously, with or without catarrhal symptoms, becoming gradually severe and dangerous. In these it is often difficult to assign the exact period of *attack*. Fatal cases most frequently begin in this manner, especially in the plethoric, cachectic, and persons accustomed to full living. In others, after a protracted and severe *premonitory stage* and indistinct symptoms of *invasion*, the fever proceeds with indications of imperfectly developed reaction, and soon assumes a putrid or malignant form. In some cases, rigors and shiverings sufficiently evince the period of attack, and quickly give rise to inordinate reaction, followed by exhaustion and evidence of change in the fluids and soft structures. Amongst the most constant of the early symptoms are—dull pains in the head, occiput, back, and limbs; universal weariness, soreness, and loss of muscular power; confusion of mind; pains in the joints and limbs resembling rheumatism; frequent sighing; nausea or vomiting; and noises in the ears.

474. The pulse, when *reaction* is developed, is full, open, quick, sharp, but soft and easily compressed. Respiration is laborious, suspirious, with oppression or anxiety at the præcordia and epigastrium. Burning heat is often felt internally, and on the surface of the trunk. When reaction is either imperfect, or does not take place, the pulse is slow, or not more frequent than usual; is weak and compressible, sometimes unequal or intermittent; and the temperature is little or not at all increased, or it is unnatural. The tongue is either loaded and furred, or flabby and covered with a dirty mucus. Thirst is generally urgent. The vascular excitement usually continues, in various grades, from six to eight days; and as it passes its acme, or about this period, purplish spots, of the size of flea-bites, and of various shades of deepness, appear upon the neck, breast, and insides of the arms and thighs. The pulse becomes more soft and weak; sometimes unequal and small. The tongue is more loaded, and of a darker colour. Thirst is diminished, or is not complained of; and the excretions present a very morbid appearance, and an offensive odour. To these are added dulness of all the senses, or delirium, alternating with stupor, difficulty of articulation, and often also of deglutition, leipthymia, faintness, and tremors. From the eleventh to the seventeenth day, but frequently earlier, the abdomen becomes tympanitic, if the disease proceeds *unfavourably*; the petechiæ are of a darker colour; vibices or blotches appear on the extremities; profuse foetid perspirations break out without relief; the posture is constantly supine; parts pressed upon quickly sphacelate; the tem-

perature sinks often below the natural standard; and the tongue is now black, fissured, or flabby, clean, dark red, or livid. Coma; subsultus tendinum; convulsions; hæmorrhage from the bowels; or exudations of a sanious fluid in the evacuations, or from the gums, lips, and nostrils; also take place towards the close.

475. A favourable change most frequently occurs from the ninth to the seventeenth day, and is indicated by profound sleep; by a warm, soft, and moderate perspiration; by turbid urine; by natural stools; and by a brighter colour, or disappearance of the petechiæ. — The duration of this fever is seldom longer than twenty-one days; but it may terminate on any intermediate day between the sixth and twenty-fourth. A fatal issue occurs most frequently from the eighth to the fourteenth. — Towards the close of an epidemic, the usual course is often departed from; mild cases of short duration, and *relapses*, amongst these especially, being very common. When mercury has been given so as to affect the mouth, a crisis is prevented, and convalescence is protracted.

476. *B. Modifications.* — *a.* Such is the more usual course of the disease, particularly as observed in modern times. But it presents various grades of severity, and several modifications and complications. It is in some cases, even in the same epidemic, comparatively mild; yet presenting manifest signs of colligation, or of a septic tendency, particularly as respects the state of vital power, the circulating fluids, and the appearance of the petechiæ. In others, the attack is violent from the commencement, and the symptoms intense; diminution of the vital cohesion of the tissues, and dissolution of the fluids, appearing early and proceeding rapidly. In many, the invasion is gradual, or much less tumultuous, than in these; the progress is more insidious, and the results are not less dangerous. In both, the body undergoes decomposition soon after death, and the rigidity usually observed *post mortem* does not take place.

477. *b.* When this fever is epidemic, petechiæ may appear as early as the third, fourth, or fifth day from the attack, in mild as well as in severe cases; and a white miliary eruption may break out at a late stage, particularly when the perspirations are copious. Yellowness of the skin, or purplish colour of the extremities, or enlargement and inflammation of the glands in the neck or groins, may occur in an advanced period. Pimples may also appear on the surface, and may be considered a favourable indication. Although delirium and insensibility generally follow the headach of the early stages, yet the mind may be serene and unaffected throughout — even to the moment of dissolution. In cases which present no distinct sign of invasion, nor of reaction, but proceed insensibly to a general colligation of the fluids and solids, the excretions, both cutaneous and intestinal, are generally abundant and very offensive: the flow even of urine being sometimes excessive. The tongue is occasionally natural; or it is clean and raw like; or as if streaked with blood, or with a bloody sanies. An aphthous state of it, and of the lips, is also sometimes remarked.

478. *c.* In persons who live fully and luxuriously, particularly if they have passed their thirtieth year, this fever often proceeds in an insidious but fatal manner. Such patients do not complain

of pain, or of much uneasiness; although they are remarkably debilitated and depressed. Their manner is somewhat hurried, but their intellect is clear. The skin is greasy, and covered with *dun petechiæ*, sometimes intermingled with white miliary vesicles; its temperature is low: the countenance slightly suffused: the eyes glassy; the tongue sometimes loaded or crusted, or clean and moist; thirst is often absent, and the pulse but little accelerated. Convulsions are frequent; and a fatal termination often ensues, mostly before the fourteenth day.

479. *C. Complications*, similar to those already described, may take place in the early stages of this disease. — *a.* The *catarrhal, bronchial, and pulmonary complications* are most common in winter. When the bronchi and lungs are seriously implicated, the respiration is short, hurried, or laboured; cough is frequent; and the sputum is bloody, rusty, or consists of a dark, sanious matter, particularly in the latter stages. — *b.* The association with *cerebral affection* is very frequent, particularly in the strong and plethoric, and in persons whose minds have been much harassed previously to the attack. These latter seldom recover from it. In this state the headach is severe from the commencement: the eyes are injected or suffused: reaction is more or less energetic, and is often attended by epistaxis, which, however, is never critical. Delirium, insensibility, subsultus tendinum, &c., are common phenomena in the latter stages of unfavourable cases. — *c.* The *digestive canal and liver* are chiefly affected in summer and autumn; the fever assuming gastric and bilious characters at its commencement, with bilious vomitings, &c., but soon passing into the putrid state. The enteric and dysenteric states are also frequent, especially at later periods of the disease. The *enteric* is the most dangerous of the abdominal complications, particularly when the petechiæ, or vibices, are of a dark, or deep purple colour; the abdomen tympanitic; and the stools are green, livid, or black, mixed with dark fluid or grumous blood. In these, fatal hæmorrhages sometimes occur. The dysenteric state may take place in mild as well as in severe cases, at an advanced stage; with severe gripings, and dark sanious, bloody, and mucous stools, which are very foetid and infectious. The disease may thus pass into the adynamic form of dysentery. This change was common in the epidemics lately prevalent in Ireland. — *d.* The complication with inflammation of the *fauces and pharynx*, or with putrid sore throat, is sometimes observed, and is to be distinguished from primary *cynanche maligna*, by its occurrence in the course of the fever, or as a contingent affection (§ 479).

480. *D.* The *sequelæ* of this fever are sometimes serious. They consist chiefly of dysentery, chronic diarrhœa, dropsies and œdematous swellings of one or more of the extremities, pulmonary consumption, hepatic obstructions, mania, and other forms of insanity, abscesses in various parts of the body, sloughing sores, inflammation of veins, particularly of those of the extremities, gangrene of the feet, rheumatic affections, &c. Most of these result in great measure from the changes that have taken place in the blood during the fever; these changes affecting the blood-vessels, and organs most susceptible of congestion. — *Relapses* are

frequent in cases of short duration, and in those which have been apparently cut short by active treatment; and are generally more dangerous than the first attack. They are more common in males than in females; and towards the close of an epidemic than at its commencement.

481. *E. Diagnosis, or the Changes which more especially constitute Malignancy or Putro-Adynamia in Fevers.* — *a.* The secretions, next after the state of vital power, indicate incipient dissolution of the vital cohesion of the blood and soft tissues. — The urine has first a more viscid and albuminous appearance than usual. It is frothy, browner, and less transparent. If this pathological condition increases, the urine becomes brown, or dark brown, clouded, turbid, muddy, and often deposits a brown sediment. It quickly becomes putrid or offensive. — The *faeces* are fetid, or have a putrid smell — are dark, fluid, ochrey, or contain blood. — The *sweat* is thick, clammy, sometimes cold, copious, and always offensive; and occasionally it imparts an ichorous stain to the linen. — The secretion poured into the mouth is a thick, viscid, slimy, dirty mucus, of a dark brown colour, that collects over the teeth, edges of the tongue, and lips.

482. *b.* The changes observed in the *vascular system* are — an open, broad, soft, compressible, undulating, or unequal, or a very quick, small, thready, and irregular pulse; a more than usually dark appearance of the superficial veins, or dark streaks in their course; and, at an advanced stage, exudations of dark, dissolved, or thin blood, or of a bloody sanies, from the outlets of canals, as the mouth, nostrils, anus, vagina, &c. — Blood taken from a vein, even previously to the occurrence of these signs, is very dark, thin, sometimes of a black purple hue; and either does not separate into coagulum and serum, or coagulates into a soft, pulraceous, or gelatinous mass, with imperfect separation of the serum. The fibrinous and albuminous constituents are deficient; and, owing to this circumstance, together with the want of vital power in the vascular system, the coagulum wants cohesion, the least agitation causing a partial admixture of red particles in the surrounding serum. — As the dissolution of the vital cohesion of the circulating fluids and softer solids proceeds, the colouring particles of the blood often fall to the bottom of the vessel, or of the gelatinous coagulum, leaving the upper stratum, and the surrounding serum, of various shades — sometimes of a greenish, purplish, or reddish hue. LANGRISH, HUXHAM, FORDYCE, HILDENBRAND, and others, have noticed a peculiar putrid odour of the blood when taken from a vein. (See BLOOD, § 110. *et seq.*) This fluid soon undergoes putrefaction after its removal from the body. It presents, however various anomalies, in particular cases, or in some epidemics; but it seldom evinces very remarkable alterations, excepting as the grosser and more palpable results of anterior changes, which, although evidently of a most important kind, admit not of precise recognition; nor do those alterations occur until the symptoms indicate depression of constitutional power, imperfect assimilation of absorbed fluids, and lesion of the depurating functions. In connection with these changes, particularly, those of the blood, the tonic, or vital cohesion, of the extreme capillaries and

softer solids are very much impaired, occasioning thereby further alterations. The functions of the cerebro-spinal nervous system are often more or less disordered, as in low nervous fevers; and the states of the mucous and cellular tissues, and of the skin, are remarkably altered. The cellular tissue becomes flaccid, softened, or less coherent, and consequently slightly tumid; and hence the bloated appearance in extreme cases; or cachectic fulness of the surface, in the most fatal states of the disease. The mucous tissue is discoloured; it exhibits a dirty brown, or grey, or livid hue, with black ecchymosed spots.

483. *c.* The *cutaneous surface* is at first merely dusky or lurid. But as vital power is further depressed, a bluish, marbled discolouration is sometimes observed in the shape of veins. *Petechiæ* of various depths of shade, from a lively or dark red, to a purplish or brown colour, appear principally upon parts usually covered by the clothes. They are either alone, or attended by the exanthematous eruption characterising the variety next to be noticed (§ 485.), or by dark or purplish spots of various sizes. In some cases, the skin, especially that of the extremities, becomes of a dark purple colour. When there is much heat of surface in the early stage of excitement, a caustic or morbid sensation is imparted, which increases whilst the hand remains in contact with it. When copious sweats follow, a white miliary eruption, intermingled with petechiæ, or vibices also, sometimes is observed. As the temperature is reduced, an unpleasant raw, cadaverous, or cold feeling is imparted to the hand of the examiner; and the petechiæ often become much darker, or more numerous, or aggregated, or almost confluent in some parts. In such cases, *passive hæmorrhages*, particularly from the bowels, are not uncommon; but they may also occur without much change in the skin. The integuments readily sphacelate from slight injury, irritation, or pressure; and may even be the seat of sphacelating sores or carbuncles in extreme cases. — Enlargement or obstruction of the lymphatic glands, with a tendency to asthenic inflammation and disorganisation of the surrounding cellular tissue, is sometimes seen in the most malignant cases; but these changes take place most remarkably in *plague*, which has been considered by many able writers as a modification merely of this fever — the one disease running into the other. (See the article on that disease.)

484. *d.* As to the *immediate causes* of, or pathological states giving rise to, the septic or putrid changes in the fluids and solids, observed more remarkably in some fevers than in others, even the most experienced writers are not agreed. There can be no doubt that these changes should be referred chiefly to the depressed state of organic nervous or vital power, and to the consequently imperfect functions of assimilation, excretion, and depuration, as insisted upon above (§ 102.), and in the article BLOOD. But the direct introduction of putrid animal or vegetable matter into the circulation, in considerable quantity, so as to depress the vital influence below the power either of salutary reaction or of excreting it through the emunctories, will so contaminate the whole mass of fluids, as to give rise to alterations and appearances very similar to those just described, and to many of the more intense symptoms pre-

viously noticed as depending chiefly upon the state of the cerebro-spinal system (§ 479.). The experiments made by GASPARD, MAGENDIE, and others (see *Lond. Med. Repository*, vol. xvii.), have proved this fact; but changes quite as malignant, as in the fever now being considered, and in plague and yellow fever, take place without any very manifest or demonstrable source whence they could have proceeded. In such cases, numerous facts and circumstances concur in showing that a morbid seminum — an infectious miasm — proceeds from the bodies of those already affected, and, through the medium of the inspired air, contaminates the blood as it circulates in the lungs, and affects the organic nervous influence. It may also be admitted, that miasms proceeding from animal and vegetable matter in a state of decay — from a number of persons breathing the same atmosphere — from those shut up in close, warm, and ill-ventilated places — will produce a similar effect, and generate a malignant *fièvre de novo*, which will be capable of propagating itself by means of the emanations evolved in its course.

iv. TYPHUS. — SYN. *True Typhus; Exanthematic Typhus; Nervous Fever with exanthematous Eruption; Contagious Typhus; Febris nervosa epidemica; F. nervosa exanthematica; F. maligna cum sopore*, Rivièrè; *F. Contagiosa; F. nervosa petechialis; F. pestilentialis Europæ; Typhus Contagiosus exanthematicus*, Hildenbrand; *T. Castrensis*, Boerhaave; *T. Gravior*, Cullen; *T. nostras*, *T. Europæus*; *T. Communis*, *T. Bellicus*; *T. Contagiosus*, Naumann; *T. Exanthematicus*; *Pestis Bellica*; *Der Ansteckende Typhus*, *Das Ansteckendefieber*, *Das Exanthematische Nervenfieber*, Germ.; *Die Kriegspest*, Hufeland; *Das Fleckfieber*, Reuss; *Typhus Contagieux*, *Fièvre d'Hôpital*, Fr.: *Fièvre adynamique ataxique*, Pinel; *Tifo Contagioso*, Ital.

485. This fever is characterized by phenomena which distinguish it from the foregoing varieties; — by catarrhal and gastric symptoms early in the disease; by stupor, delirium, or typhomania; by a peculiar cutaneous eruption: by more or less evident affection of the liver; and by the determinate course and regular succession of all the febrile changes.

486. True or contagious typhus has been confounded with synochoid and nervous fevers, on the one hand, and with putrid or malignant fever, on the other. It has been already stated, that putridity or malignancy not only may characterise a particular form of fever or certain epidemics, even at an early period of their course; but also, owing to various contingencies, may take place in advanced stages of any other fever. As the circumstances favouring the generation and spread of typhus are often such as also tend to develop those changes which have been usually named putrid or malignant, and as these changes are frequently observed in the latter stages of typhus — the symptoms distinguishing this fever becoming associated with, or followed by, those indicating the putro-dynamic state — so has it been often confounded with other fevers, in which this state has predominated more or less. If we refer to the numerous histories of epidemic typhus recorded by writers from the close of the fifteenth century up to the present time, or even to the brief abstracts furnished by M. OZANAM (*Hist. Méd. des Ma-*

ladies Epidémiques, &c. t. iv. p. 155. et seq.), we shall find, that although many of these, owing to the concurrence of circumstances developing a putrid or malignant disease, were instances of fever, either identical with, or very closely resembling, that which I have described as such in the preceding section; yet many others — or even the majority — were true typhus in which the putro-dynamic state was either early or prominently developed; the exanthematous eruption characteristic of typhus being succeeded or accompanied by the petechiæ indicating the approach of the septic condition, and being either mistaken for them, or for an eruption of miliaria. Owing to this circumstance especially, typhus, low nervous, and putrid fevers have been very generally confounded together. The essential characters of typhus were first distinctly traced by SAUVAGES; but CULLEN mixed them up with the symptoms of those forms of low nervous or typhoid fever which occur sporadically. Even among modern writers, comparatively few have made the distinction, excepting HILDENBRAND, FODÉRÉ, NAUMANN, PEEBLES, and some others. True or contagious typhus has not been epidemic in England for many years; or, if it have appeared in a few places, it has not extended beyond them. In Ireland, however, it was extensively prevalent, particularly in the years 1817, 1818, and 1819; and in some parts of Scotland since that time. The fevers most commonly observed in England, and particularly in London, have been either synochoid, simple, or complicated; or low nervous fever variously associated, and but rarely displaying a predominance of putrid or septic characters. During 1836, 7, 8, and 9, this fever was very prevalent in London, and in several other places.

487. True typhus, although prone to assume a septic condition, especially when epidemic, and appearing under the unfavourable circumstances about to be noticed, yet may run its whole course without petechiæ or any marked putrid symptom. It may, as shown by HILDENBRAND, be simple, or variously complicated; and, as remarked by Dr. PEEBLES, it may be benign throughout, or assume a malignant character, according to individual diathesis, the nature of the prevailing epidemic, or the mode of treatment. It generally presents itself as an epidemic, is contagious, and runs a uniform course, unless predominant affection of some internal organ modifies its course or prolongs its duration.

488. It has been shown above, that the petechial affection consists of minute stains or ecchymoses, caused by the transudation of blood from the minute capillaries of the vascular rete of the skin, owing to the atony of these vessels and the alteration of the blood; that it may occur in the advanced stage of any fever, even of the more inflammatory or purely eruptive, when converted into an adynamic or typhoid state, by improper treatment or the peculiar condition of the patient; and that it is not, in any sense of the word, an eruption, as it has been very improperly denominated by some writers. This change in the skin, which has been viewed as one of the chief indications of incipient putridity, or of a septic tendency, is very different from the eruption characterising typhus. The petechiæ, or cutaneous ecchymoses, vary in dimensions from

minute *stigmata* to large patches or *vibices*, and in the deepness or shade of colour. They very rarely appear at the commencement, even of the more putrid or malignant fevers, unless from peculiar depravity of constitution, or from causes affecting more especially the circulating fluids — as impure air, imperfect nourishment, unwholesome food, or other injurious ingesta.

489. But the *exanthematous eruption* attending true typhus, is as characteristic of it as the eruptions of measles or of scarlatina; and, although observed by numerous writers, it has been confounded with petechiæ, with which it is often associated in the advanced stages of the fever, or with military eruptions. — HILDENBRAND gave a description of it, as it appeared in the contagious fevers prevalent in Germany during the commencement of the present century; and Dr. PEEBLES has recently described it accurately and minutely, and as he saw it in Italy, soon after the war. His description agrees with my own observations about the same period. This eruption appears in the early progress of a fever produced by human effluvia, when circumstances occur to promote them, or to prevent their dissipation. The animal miasm, whether generated by numbers crowded in a small space and confined air, or proceeding from a person affected by the disease, should be viewed as a poison, affecting the human body in a specific manner, and causing fever with an eruption of a certain form, which propagates itself by the diffusion of a morbid effluvia in the surrounding air, or by its retention in various animal productions or porous substances when shut up from the air.

490. This eruption usually appears from the third to the seventh day of the fever, but it may be delayed till the twelfth or fourteenth day. It is of a florid, reddish, or reddish pink colour; disappearing on pressure, but soon returning when pressure is removed. This circumstance is sufficient to distinguish it from petechiæ. The more exuberant resembles the measles, and has been mistaken for them; but it is more papillar, and rougher to the touch, being sensibly elevated to the eye; and, although sometimes grouped or crowded, it does not coalesce so much as measles, but each papilla is more or less separate. It is sometimes vesicular, and followed by desquamation of the cuticle. It is occasionally indistinct, and may be then overlooked, and it sometimes approaches more nearly the military eruption. Hence it has been mistaken for this eruption in such cases. It is generally confined to the trunk of the body, the arms, and thighs, but it may cover nearly all the body. It rarely extends over the face or hands. In children, it appears only upon the trunk, or parts of it, and often scantily. It is sometimes evanescent, disappearing in one part of the body and returning in another (PEEBLES.) It may be copious in some cases, and scanty in others, even in the same family. Owing to these circumstances, it may escape observation. It is not liable to recede early in its course; but if it disappear from injudicious treatment, or a faulty state of the system, malignant symptoms are apt to supervene.

491. In some cases, the interstices of the skin between the papillæ are red or erythematous. In these, there are also increased suffusion of the eyes, redness of the tongue at the point and edges,

redness of the fauces, as in mild scarlatina, and subsequent desquamation of the cuticle. The duration of this eruption is from three to five days. When the exantheme is slight, it disappears without leaving discernible marks; but when it is exuberant, stains are left in the situation of the papillæ. If petechiæ occur in this fever, they seldom are observed before the eighth or tenth day, and then this eruption has usually disappeared. When the petechiæ are earlier, or the eruption continues longer, so that both exist together, they are quite distinct and different in their appearances; for the latter is never so dark or livid as the former generally is, and the petechiæ are not attended by the elevation of the cuticle and roughness characterising the eruption. The stains left by an exuberant eruption generally become livid when petechiæ are present; but the eruption itself does not assume a dark tint, as long as it retains its papillar form. In the more malignant cases, and when petechiæ appear early in the disease, the colour of the eruption may, however, become deeper, or may change with the alteration in the fluids and softer solids.

492. A. DESCRIPTION. — True typhus proceeds in a more regular and determinate manner than synochoid or nervous fevers; and presents the several stages into which I divided fever, when treating of it generally. — a. The *premonitory stage* exhibits the same symptoms as are observed to announce other fevers, and varies much in duration. HILDENBRAND states from three to seven days; but a much longer time may elapse from the time of infection to the occurrence of the *stage of invasion*. This period is the commencement of the febrile paroxysms. It begins with a creeping sensation over the head and back, followed by shiverings, paleness of the surface, the cutis anserina, intervening flushes of heat, heaviness or giddiness of the head, and the usual symptoms of this stage. — b. After a few hours — seldom more than twelve — the *stage of reaction* — the *inflammatory* of HILDENBRAND, the *irritative inflammatory* of GOEDEN — appears. The pulse becomes full, strong or oppressed; the countenance flushed; the skin hot and turgid; the head confused, heavy, or giddy; and the urine scanty and high-coloured. With these are associated catarrhal or gastric symptoms. — On the second day of this stage, after a sleepless and restless night, the heat increases, while the vomiting and sometimes the nausea disappear. The weight in the head changes to stupor, often with *tinnitus aurium*; giddiness is augmented, and the upright posture cannot be borne. The catarrhal affection is more developed: the eyes are red; the mucous membrane of the nose and fauces is tumid and red; deglutition is painful; tightness is felt in the chest, often with cough; and both hypochondria are tense and painful. The patient is averse from exertion, tardy in his answers, silent as to his complaint, and slow in protruding his tongue. These symptoms continue during the third and fourth days. On the latter of these, an exacerbation takes place, usually followed by a moderate epistaxis, excepting in the milder cases, and generally with relief of the affection of the head. From the third to the sixth day, but sometimes later, the surface of the body becomes turgid and the eruption appears. During the fifth, sixth, and seventh days, the symptoms are unchanged, excepting that the catarrhal af-

fection commonly ceases with the appearance of the eruption. On the seventh day an evident exacerbation takes place, followed by a slight remission of a few hours, and introduces a new stage.

493. *c. The nervous stage — the status nervosus of HILDENBRAND* — begins with the eighth day from the occurrence of rigors. The heat of the surface is now considerably increased, but the turgidity disappears. The epidermis is dry, shrivelled, and brittle; but petechiæ or miliaria are frequently present, and either appear in the latter part of the preceding stage, or early in this: The tongue, which was at first clean, and subsequently white, rather than loaded or furred, now becomes parched and shrunk. Thirst is increased; but the torpor is often so great that the patient does not ask for drink. The tightness of the chest goes off, and the breathing is freer, but more frequent. The cough ceases, and is often replaced by singultus. Swallowing is impeded, chiefly owing to the dryness of the fauces and pharynx. The bowels now assume activity — predominant action being determined to them in place of the skin. Repeated, loose, fœtid stools occur, attended by slight pains in the bowels, and by flatulent distension of the abdomen, evidently owing to increased vascular action. The pulse is variable; it generally continues full, free, not very frequent, nor small or soft; and it often indicates imperfect reaction or contraction after the heart's impulse, or seems to be in a state of constant expansion. The most prominent, however, of the symptoms in this stage are those referrible to the sensorium. In the preceding stage the external senses are impaired, and the ideas confused. There are sleeplessness, restlessness, and some involuntary motions. These are all aggravated or modified in this period. Muscular power is suppressed by the general torpor of the nervous system, rather than by debility, as in a state of intoxication; but the involuntary motions, such as tremors, subsultus tendinum, slight convulsions, or spasmodic affections, are increased. Difficulty of deglutition, and of evacuating the urine, is more common; deafness is increased; vision is impaired; and smell and taste are lost. The patient dreams without being asleep (*typhomania*), talks deliriously, is occupied with his internal impressions, and disregards or is unimpressed by external objects, or confounds internal and external perceptions. A single idea or impression usually torments the patient during the fever, and on recovery there is seldom any recollection of it. This state closely resembles somnambulism. With insensibility to external objects, there is complete loss of the appetites and desires; the patient wishes and feels nothing, and replies, when roused, that he is very well. This stupor, in various degrees, with the supine posture, at once announces the form of the disease. The foregoing symptoms continue during the ninth and tenth days. On the evening of the latter day a stronger evening exacerbation than usual occurs, and lasts for a few hours; and a gentle perspiration, or some evacuation by stool or urine, takes place. A slight remission follows on the eleventh day; but on the twelfth and thirteenth, febrile heat, and the affection of the nervous system, are again increased.

494. *d. The period of crisis* now generally succeeds, and without any assistance from art. At

the end of the thirteenth day, a more severe exacerbation than any former one takes place: the heat is more glowing; the arteries pulsate more strongly; the brain is more affected; and the stupor passes into sopor. In twelve hours afterwards, and on the fourteenth day, the parched skin shows a tendency to perspiration. In some a slight epistaxis occurs, with relief to the head; the nostrils become moist; the tongue at the point and edges moist, clean, and red; and perspiration more copious and general. A free expectoration often takes place, especially if the chest has been affected. When the perspiration is salutary it is uniform, not clammy, has a peculiar smell, and occurs during sleep. The stools are now copious, loose, and offensive; and the urine plentiful, muddy, high-coloured, and deposits a copious sediment. With these changes, or in a few hours afterwards, the patient seems as if he had awakened from a dream, or from a state of intoxication; and, with a return of complete consciousness, all the severe symptoms abate. A sense of fatigue and weakness, soreness of the whole body, pale hollow countenance, giddiness, deafness, and *tinnitus aurium*, drowsiness, or frequent inclination to sleep, tendency to perspire, quick pulse, and acceleration of it upon slight irritation or exertion, unnatural taste in the mouth, whitish tongue, &c., remain for six or seven days after the crisis — these symptoms gradually disappearing, the *tinnitus aurium* last of all.

495. *B. Modifications and complications.* — As in exanthematous fevers, so in this, variations from the regular type, both in the symptoms and in their course, are apt to occur, owing — 1st, to the age, habit of body, previous health, and temperament of the patient; 2dly, to the prevailing epidemic constitution, whether inflammatory, bilious, or tending to the periodic type; and, 3dly, to the living, diet, and treatment, and to the unfavourable circumstances to which the patient is exposed. — *a. The anomalous phenomena* observed in the *stage of invasion*, are few. The shivering may be so slight as hardly to be observed; the fever seeming to begin at once with increased heat; or the rigors may last or return at intervals during some days. — In the *period of reaction* the modifications are often more numerous and striking. The inflammatory character of this stage is often greatly increased; sometimes as respects the violence of the general symptoms, but at others with severe local affection. When the *head* is the seat of prominent action, the delirium may be phrenitic, maniacal, or the stupor may amount to apoplectic sopor. Inflammation may take place, either in the *lungs*, or in the *liver*, or in the *digestive mucous surface*, and be so fully developed as to resemble idiopathic disease of the viscera, if the previous fever, stupor, *tinnitus aurium*, and peculiar eruption, did not establish the difference between them. — *Bilio-gastric* affection, also, may be so prominent as to simulate that form of fever. But the stupor and typhomania will assist the diagnosis, should the eruption be so slight as to escape observation. The *nervous* character may show itself prematurely; especially when the vital powers are weak, depressed, or speedily exhausted. In these, *septic* or *malignant* symptoms may occur. In some cases, the inflammatory stage may continue to the ninth or even to the eleventh day.

496. *b.* In the *nervous stage* various modifications are also observed. Local affections may continue through the greater part of this stage, or may even first appear in it; particularly those seated in the intestines, and implicating especially the mucous follicles. Diarrhœa, or typhoid dysentery, may thus supervene, and be either slight, severe, or fatal. The former of these affections is caused by vascular determination to the intestinal mucous surface, consequent upon the subsidence of the eruption, and by the unhealthy bile secreted by the irritated liver from the impure blood circulating in it. The dysenteric symptoms are owing to the morbid action going on in the lower part of the ileum, in the cæcum, and large bowels. Lumbrici are sometimes passed. But the principal and most frequent variations consist in the appearance of numerous *petechiæ* and *vibices*, or in their increase or deeper hue, if they had previously been observed, with several other putro-dynamic changes. In these, the nervous symptoms may not be more remarkable than in milder cases; or these symptoms may be very prominent, either with or without the occurrence or aggravation of the malignant or septic state. Miliary eruptions may also appear in this stage. In the more unfavourable cases the tongue may be shrunk like a piece of burnt leather, the heat of surface excessive, the diarrhœa exhausting, the distension of the abdomen great, and pains in the bowels severe. *Muscæ volitantes*, picking of the bed-clothes, constant muttering, spasmodic affections, stiffness or cramps of the extremities, paralysis of the eyelids or tongue, horror at liquids, may also occur. A black coating of the tongue and teeth; fetor of the breath, stools, and of the body; dark *petechiæ* or *vibices*; ecchymoses or bluish patches; passive hæmorrhages, and even carbuncles, may appear during this stage, particularly when circumstances concur to produce putrid or septic changes in the course of the fever. These severe cases, if they are not fatal before the fourteenth day, often run on to the seventeenth, twenty-first, or twenty-eighth day, and generally end in death.

497. *c.* Sometimes the *præcrisis* on the seventh day either does not take place, or is not followed by any alleviation, or is attended by aggravation of the symptoms. If a decisive *crisis* take not place on the fourteenth day, it rarely happens till the twenty-first; a crisis between these days being seldom effective. When death occurs, the fatal change is either premature or procrastinated. The symptoms accompanying a crisis are often variable. Changes in the urine cannot be depended upon. Discharges from the bowels are often copious, without benefit; and if they continue so without alleviation of the symptoms, or are unnatural, ulceration of the intestinal mucous surface may be dreaded. A critical sweat is sometimes wanting, the patient recovering nevertheless.

498. *d.* The *decline* of the disease may be protracted, but never shortened; and attended by various symptoms, as a continuation of the stupor, nightly recurrence of delirium, or lingering affections of some one of the thoracic or abdominal viscera. A new disease, of an inflammatory kind, may occur during the stages of decline and convalescence, or tubercular consumption may supervene; and *relapses* are not infrequent in the

latter period, owing to a fresh infection. — *Recovery* may be retarded by the severity of the complications, by want of sleep, by errors in regimen, and by the depressing passions.

499. *e.* The foregoing modifications refer entirely to aggravating circumstances; but some cases are so slight, that the patient scarcely keeps his bed—a trifling degree of stupor, with scanty eruption, and occasional pains in the bowels, constituting the chief complaint. In the more benign cases a decisive crisis occasionally takes place as early as the eleventh, or even the ninth, day; but *relapses* are liable to follow if the patient be exposed to a re-infection.

500. *v. CAUSES.*—*A.* The causes of typhoid fevers differ but little from those of the synchoïd forms. — *a.* The *predisposing causes* (§ 446.) of both are the same. Although typhoid fevers most frequently occur in persons from 15 to 40 years of age, yet the mortality, in proportion to the number affected, is much less in this than in more advanced periods of life. The predisposition to be attacked diminishes remarkably with advancing age, especially after 50; but the proportion of those who die increases in a still greater ratio. The predisposition also diminishes as we descend from puberty to infancy, and the mortality diminishes in a still greater ratio. Thus children and aged persons are least obnoxious to typhoid and infectious fevers; a somewhat different law here obtaining from that which characterises the operation of exhalations from the soil upon the human constitution; these latter affecting the young and old as well as the middle-aged, and renewing their attacks in various forms, whilst typhus fever seldom occurs oftener than once in the same person.

501. *b.* The *exciting causes* of typhoid and synchoïd (§ 449. *et seq.*) fevers are often the same, excepting that infectious miasms, want, and famine, the various contingencies connected with the operations of war, and epidemic influences, are most concerned in producing the *severer varieties* about to be described.—The *sporadic cases* of this fever, and which generally present either the milder form, or most of the nervous character, often originate in the depressing passions, in changes from the usual habits and modes of life, or in exposure to novel influences, physical and moral; in weak delicate persons of a lax habit of body; in persons imperfectly fed, or reduced by previous disease, or by exhausting discharges, &c. From these causes especially proceed the adynamic, slow nervous, or mild typhoid fevers, often observed in persons who have recently removed into large cities, or who live in crowded, low, and ill-ventilated apartments. — The *epidemic visitations* of typhoid fever are usually of the more low or severe forms described hereafter.

502. Although nervous and typhoid fevers arise from animal or infectious miasms, yet they proceed also from other causes, as shown above (§ 452. 501.) especially mental emotions, and impure air. The more complicated and putro-dynamic states of those fevers may be consequent upon other forms of fever, or upon fevers differently characterised at the commencement; but they may also arise from infectious exhalations, or more immediately and sporadically from terrestrial emanations, or from the effluvia produced by animal and vegetable matters during decomposition, particularly in a close, warm, and humid air; or from a combina-

tion of causes both internal or intrinsic and external, as respects the patient; and they may subsequently extend themselves by the infectious miasms generated in their course.*

503. B. — The chief cause of true typhus has been already stated to be an animal miasm, generated either by a number of persons confined in a close air, or by the disease itself. This miasm contaminates the air, and infects the healthy frame through the respiratory organs — either directly as it proceeds from the morbid source, or indirectly by means of substances capable of retaining it for a time, and of giving it out upon exposure to the air. The causes predisposing to, or counteracting, infection, are deserving of a brief notice. Infants and old persons are the least susceptible. Adults, of delicate habits and melancholy disposition, and those who dread infection, are most liable to be attacked. Insufficient or unwholesome nourishment, personal or domestic filth, and bodily fatigue or mental distress, are very influential concurring causes. Persons of a lively disposition, those who use tobacco, and who have no fear of the disease, most frequently escape. Chronic diseases, particularly those of the lungs, ulcers, and external sores or eruptions, are very often preventives. HILDENBRAND states, that, in his very extensive experience, he never saw a consumptive patient contract the disease. A regular and fully developed attack seems to prevent a second, for many years afterwards, if not for ever.

504. C. — The Causes of both Synchooid and Typhoid Fevers are most active, or abound most, — are longer retained and more rapidly spread, — in large cities, or in manufacturing towns, especially in low-crowded, foul, close, and ill-ventilated parts of these towns. This fact, already well known, has been ably illustrated by Dr. COWAN. In the large manufacturing city of Glasgow, these fevers have been lately more prevalent than in any other part of Great Britain. This has been the case since 1815, and more particularly since 1824. A nearly equal prevalence of these fevers in Edinburgh since 1831, has been shown by Drs. ALISON and CHRISTISON. Dr. COWAN estimates the numbers of cases of fever in Glasgow in 1835, 1836, and 1837, at 6180, 10,092, and 21,800 respectively, one-third of which cases was treated in hospitals. The epidemic prevalence of fevers in Glasgow and Edinburgh is favoured, beyond what is observed in the large manufacturing towns in England, by the much lower living of the poor, and by the want of due provision for the necessitous in the former places. The diminished prevalence of fever with advanced age, remarked upon above, (§500.), has been well illustrated by Dr. COWAN in his researches into the statistics of the epidemic of Glasgow in 1836. He adduces the following table of the relative population and relative numbers of cases of fevers at different ages admitted into hospitals.

Age.	5 to 10.	10 to 15.	15 to 20.	20 to 30.	30 to 40.	40 to 50.	50 to 60.	above 60.
Population	25,707	21,211	20,745	38,185	26,419	18,014	11,648	10,220
Fevers	191	318	501	715	309	128	43	11

According to the observations lately made both in Edinburgh and Glasgow, the prevalence of synchooid and typhoid fevers in both sexes appears to have been nearly equal.

505. XXIII. PROGNOSIS, TERMINATIONS, MORTALITY, and ORGANIC CHANGES IN SYNCHOOID and TYPHOID FEVERS.—i. PROGNOSIS.—The prognosis will be influenced by the appearance of any of those phenomena to which attention has been directed above (§418. *et seq.*). But in addition to these, the practitioner will take into the account the

previous condition, the age, and the sex of the patient; the nature of the prevailing epidemic; and the influences continuing to operate during treatment. As to the manner in which age should affect the prognosis from the beginning, some very interesting facts have been adduced by Dr. ALISON, who has given the following table in illustration of the comparative prevalence and mortality of typhoid fever at different ages, as observed in his practice:—

	Cases.	Deaths.	Proportions.
Under 15 years	83	2	1 in 41½
15 to 30	149	11	1 in 13½
30 to 50	93	17	1 in 5½
Above 50	17	7	1 in 2½
Total	342	37	1 in 9¼

Of these 342, there were 170 cases of simple or mild typhus, in which only three deaths occurred; 79 cases presenting prominent affection of the head, and in these 21 were fatal; 58 cases with affection of the pulmonary organs, in which 13 were fatal; and 35 with abdominal affection, in which only one death occurred. — From these, as well as from other data and facts which have come before every experienced physician, it may be inferred that the mortality from this fever increases in an accelerating ratio with advance in age and predominant affection of vital organs. It is very probable, that the great increase in deaths at an advanced age proceeds from the circumstance of the powers of life being then less able to resist the changes and tendency to death that take place in the course of the disease, and the contamination of the fluids and soft solids: and from certain internal organs having then become highly predisposed to serious functional and organic lesions.

* A gentleman far advanced in age, on ascending the steps leading to the entrance of a chapel in this city, underneath which the bodies of the deceased members are buried, was suddenly struck by a gush of foul air which issued from the grated openings, leading from the place of burial, on each side of the steps. He instantly felt sick and faint, and after a short time was obliged to leave the chapel. The following day (Monday), he was confined to his house; and complained of aching pain of the back, limbs, and joints; of sinking and anxiety at the epigastrium and pectoria; of giddiness, confusion of intellect, and of chilliness, and great depression. I saw him on Tuesday. In addition to these symptoms, there was great prostration of muscular power: his pulse was quick, weak, and unequal, but not above 100; his tongue was loaded with a brownish fur, and dry; his bowels constipated; his skin dry, harsh, and unhealthy in its aspect; his countenance anxious and sallow. The disease proceeded very nearly as described above (see 473. *et seq.*), and he died on the eighth day of my attendance, and about the eleventh from exposure to its cause. His wife, also far advanced in age, and who had continued to sleep with her husband during the first three days of the disease, was similarly attacked two days afterwards, and three days before his death. Her symptoms throughout were entirely similar to those of her husband. She also died on the eighth day of the disease. The bodies of both rapidly went on to decomposition, although the weather was very cold. Disinfecting means were employed as soon as the nature of the fever was manifested, and no other person was infected.

506. Typhoid fevers are seldom dangerous to children in any class of society, although they are often attacked when the disease is epidemic. In the upper ranks, and in those accustomed to live fully and luxuriously, they are very fatal, and generally assume highly inflammatory states in the early stages, or septic changes at a later period. In the epidemic in Ireland, during 1817, 1818, and 1819, from one fourth to one half of those in good circumstances, who were infected, died. Of twelve physicians who were actively engaged in the treatment of the fever in Cork, eleven were seized with it, and four died. They are much less fatal to females than to males; but pregnant women often miscarry when they are attacked. In an equal number of males and of females affected, the deaths may be stated to be in the relative proportion of eleven of the former to seven of the latter. Persons whose minds have been very much harassed or exerted previously to infection are in the greatest danger. The putrodynamic form, and next to it the low or complicated nervous, are the most dangerous of typhoid fevers. These fevers, particularly when epidemic and under circumstances favouring infection, are extremely fatal to the dark races, and especially to negroes. The circumstances more particularly indicative of the prognosis has been fully discussed above.

507. ii. THE TERMINATIONS OF SYNOCHOID AND TYPHOID FEVERS vary remarkably, according to the peculiar features of the epidemic, the locality in which it prevails, the classes of society which it especially attacks; to the age, sex, previous health, and circumstances of the infected; to the numerous extrinsic and intrinsic circumstances of the attacked; and to the contingent occurrences and concurrent causes connected with the appearance of any form of those fevers.—A. Recovery, however, takes place in the great majority of cases of these fevers, even when left to nature. Treatment influences chiefly the amount of that majority, and, unless when very injudicious, not in so remarkable a degree as usually supposed. The causes which prevent this issue, are those which, singly or conjointly, favour a fatal termination; and are chiefly, 1st. treatment of the patient in unfavourable circumstances, as in a foul, close, or infectious air; 2d. exhaustion of vital power and of irritability; 3d. local complications proceeding to organic lesion; 4th. contamination of the circulating and secreted fluid; and 5th. officious interference on the part of the medical attendant.

508. B. Although death is most commonly the result of these changes, yet visceral disease, remaining after recovery from the fever, and either gradually disappearing, or becoming more and more fully developed until life can no longer be sustained, is sometimes consequent upon one or other of them. This is, however, a much less frequent termination of the fevers proceeding from animal infection than of those arising from terrestrial emanations.

C. 509. Death is generally caused by two or more the above circumstances; seldom of one of them only, although either may be mainly concerned in causing it. When death is produced by inflammation of the brain or of its membranes, during the stage of reaction, or by simple or inflammatory congestion, in this or the subsequent stage, symptoms of an irritated or inflammatory state of the brain, passing more or less rapidly into apoplectic

sopor, precede the fatal issue. In these, the blood-vessels of the brain and membranes are engorged, sometimes with extravasation of serum, or of sanguineous serum, or more rarely of blood. The patient sometimes dies soon after a critical exacerbation, from the sudden occurrence of the apoplectic state. In this case the brain is only slightly congested, with little or no effusion of fluid. In those who die with cerebral affection in an advanced period of the disease, collections of serous fluid in the ventricles, and between the membranes of the brain, are frequently found. Abscesses in the substance of the brain are met with in rare instances. HILDENBRAND considers nervous apoplexy to be the most frequent cause of death in exanthematic typhus. This only occurs in the latter days of the disease, preceded by the symptoms of the nervous stage, a fatal result taking place suddenly. As it usually happens on critical days, it may arise from the exacerbation which then occurs, wholly exhausting the nervous powers; particularly as no morbid appearances, at all adequate to account for death, are observed on dissection. It differs but little from death by debility, excepting that the latter mode takes place gradually and slowly. When debility or exhausted irritability, the state of the blood, or lesions of the intestines, cause this termination, the stupor and delirium generally cease, and the patient recovers his consciousness just before death.—Upon dissection, in these cases, no morbid appearances, beyond slight congestion, or a somewhat increased quantity of fluid in the ventricles or at the base of the brain, are observed within the cranium; the digestive mucous surface, and the blood in the large vessels and cavities of the heart being most altered.—Medical treatment, if not very judiciously directed, may be as injurious as beneficial, by interrupting the regular succession of morbid phenomena, and preventing those changes from taking place that are conducive to recovery. An officious interference may thus be mischievous, particularly when the disease is regular or moderate, and no vital organ is very severely affected. Medical treatment will not shorten the disease; we can only expect to conduct it to a successful issue, by protecting internal organs from injury, when they experience the onus of morbid action, and by resisting the tendency to death in the last stages.

510. A fatal issue is evidently caused or accelerated, in some cases, by the severity of the associated disease of the respiratory organs, preventing the necessary changes from being effected in the blood circulating in the lungs. It proceeds in others chiefly from the influence of the morbid blood upon the weakened irritability of contractile tissues, and particularly of the heart; and, in rare instances, from perforation of the intestines inducing general peritonitis, which soon exhausts the remaining powers of life. The lesions of the digestive mucous surface evidently assist in producing this effect; but in a much less degree than the depression of organic nervous power and of irritability, and the deteriorated state of the blood, with which they are intimately connected, and of which they are important effects. All these internal lesions evidently commence in the course, or even not until the advanced stages, of the disease; and, when developed, are analogous to the sphacelated sores and other alterations

which take place in external parts in the more malignant cases. These internal as well as external lesions depend upon the anterior changes in the organic nervous power and irritability, and in the blood; they present similar characters; and, where even the slightest external lesions are observed, the existence or occurrence of those that are internal is to be feared. The most constant of these latter are discolouration and diminished cohesion of the intestinal tunics, distension of the intestinal tube by flatus, and enlargement and ulceration of the follicles, with inflammation or engorgement of the mesenteric glands. There are various other lesions associated with those; but they are different in different cases.

511. iii. THE RATE OF MORTALITY in these fevers, necessarily differs with the circumstances just alluded to. It is obvious that the rate will be high in hospitals which receive cases at an advanced stage of the malady, and to which the worst cases are sent. Not only does the mortality vary with the form of fever and its complications, with the prevailing epidemic, with the season, and with the numerous circumstances predisposing to, and aiding, the exciting causes, but also with the influences which come into operation during the progress of the malady. Hence the great differences in mortality observed by writers in different fevers and epidemics. Dr. ALISON found the mortality at all ages, 1 in 9 $\frac{1}{2}$; Dr. CHRISTISON 1 in 10 in 1837, and 1 in 6·27 in 1838. Dr. COWAN states the deaths to have been 1 in 15 in Glasgow during 1835, 1 in 12 during 1836, and 1 in 10 during 1837; the rate of mortality in Glasgow and Edinburgh during this last year being the same. HILDENBRAND estimated the deaths in exanthematic typhus at one in 10. Dr. BARDSLEY observed the mortality in typhoid fevers, in the Manchester hospital to vary from 1 in 12 to 1 in 6 $\frac{1}{2}$, the average being 1 in 8 $\frac{1}{4}$. It has been supposed, that a great increase of deaths from fevers diminishes the numbers of deaths from other diseases; but Dr. COWAN has proved, by documents of what has been observed in Glasgow since 1813, that during the prevalence of epidemic fevers in that city, the mortality from other diseases may be greatly increased. In 1835–6–7, the deaths from fever were 412, 841, and 2180 respectively, and from other maladies, 7198, 8441, and 10,270 respectively, constituting, in relation to the mortality caused by other diseases, 1 in 15·6, 1 in 10, and 1 in 4·7 annually; and to the population 1 in 570, 290, and 116.

512. iv. THE ORGANIC LESIONS are not confined to any single viscus, in any one form of synochoid or typhoid fever.—a. M. CHOMEL gives the following as the results of a very careful inspection of the *encephalon* in 38 cases of typhoid fevers.—Injection of the membranes in 4; œdema of the membranes, in 7; very slight general softening of the brain, in 6; effusion of serum in the ventricles, varying from a drachm to half an ounce, in 12; numerous red points upon dividing the cerebral substance, in 5; increased density of this substance, in 2; and the normal condition, in 15.

513. b. The *mouth*, *tongue*, and *pharynx* are frequently covered with a thick mucus, underneath which the mucous coat is often not manifestly altered. But in some cases this coat is softened, discoloured, and studded with a few small round or oval ulcers, most of them not referrible to the

follicles. The *œsophagus* occasionally is excoriated or slightly ulcerated. The *stomach* is variously coloured in its internal surface. It is sometimes pale, most frequently red in various grades, or purplish or brownish red, occasionally yellowish; and often the parts of the organ in contact with the liver and spleen have imbibed the colour of these viscera.—*Softening*, or diminished cohesion, of the mucous and submucous tissues, throughout the greater part of the large curvature, or even the whole of the stomach, is observed in a large proportion of cases. The softening seldom extends to all the coats. Sometimes the mucous tunic is not only softened, but entirely destroyed, the cellular tissue or the muscular coat being denuded. It is generally easily detached from the subjacent parts. M. CHOMEL found, of forty-two cases, more or less extensive softening in fourteen. He remarks, that he observed softening of the internal coats of the stomach in the same proportion of fatal cases from small-pox.—*Thickening* and great *tenuity* of the mucous coat have also been seen, but not so frequently as softening. Although M. LOUIS met with ulceration of the mucous membrane of the stomach in four cases, and M. ANDRAL in ten, yet M. CHOMEL did not find one instance in the forty-two inspections of which he has given the details.

514. c. The *duodenum* and *jejunum* have occasionally imbibed the colour of the bile or of adjoining viscera. They are generally of a deeper red than the rest of the intestines. The *ileum* is usually more or less red, with numerous arborisations on the external surface; but more frequently the redness is seated chiefly in the mucous coat, and particularly in the margins of the valvulæ conniventes. In many cases the redness is disposed in zones, between which the three coats of the intestine present a remarkable pallor. The redness and injection are not greater around the ulcerations and tumid patches of agminated follicles, than in other parts. Alterations of colour are not so common in the large as in the small intestines, the former presenting chiefly reddish-brown patches or ecchymoid spots, or dirty purplish or brown-coloured tints. *Dark discolouration* of the small intestines, as already noticed (§ 510.) is very general. *Softening* of the mucous surface of the bowels, in the situation of the agminated follicles, or in the intervals between them, is seldom very great; the subjacent cellular tissue more frequently and decidedly presents this change. *Induration* is never observed in the digestive canal after typhoid fevers. In several cases the mucous coat is remarkably *tumid* or thickened, presenting a gelatinous aspect, and various shades of colour from a bright red to a reddish black. This change varies in extent from two or three inches to as many feet, but is quite continuous, extending around the intestine. It is most frequently found in the ileum, but it may occur in any part of the small or large bowels. It arises from the infiltration of fluid blood into the mucous and submucous tissues; for, upon pressing the part, the blood exudes through the pores, leaving the mucous coat almost in its natural state. M. CHOMEL observed this lesion in seven out of forty-two cases, and in all these there was hæmorrhage, either from the bowels or into them. He also remarked it in other diseases, wherein intestinal hæmorrhage had occurred before death.

515. *d.* Since PETIT and BRETONNEAU directed attention to the almost constant change in the *intestinal mucous follicles* in typhoid fever, the subject has been further illustrated by the researches of LOUIS, ANDRAL, BRIGHT, CHOMEL, and others. But, although this lesion is so constant in the low fevers occurring in Paris and some other parts of France, it is certainly not so frequent in the same states of fever in this country; and, instead of viewing it as intimately connected with the nature of these fevers, I consider it as only one of several changes superinduced in the progress of the disease, but one of the most frequent and important. The first alteration which these follicles present is enlargement or engorgement, owing to the formation under the mucous coat of a yellowish-white matter, slightly friable, which imparts to the agminated follicles the appearance of a thickened patch, and to the isolated follicles that of a pustule. To this state, which is generally preserved till the twelfth or fifteenth day, succeeds, in most cases, ulceration, beginning either in the mucous surface, and extending to the whitish matter, or in this latter, which becomes softened and detaches the mucous coat from the parts underneath. These grades of lesion in the follicles almost constantly commence in those nearest the ileo-cæcal valve. From the eighth to the fifteenth or twentieth day the agminated patches, which have not experienced the above changes, present a reticulated appearance; their mucous covering being of a deeper colour than natural, softened, partially detached, and perforated by numerous orifices of enlarged follicles. In proportion as these patches disappear by ulceration or by sphacelation, the margins of the ulcers become either more level, evincing a disposition to cicatrization, or more elevated, owing to thickening of the submucous and muscular tunics. The ulceration generally extends in width and depth, and successively invades the submucous, muscular, and serous coats; ending at last in perforation; but death most frequently takes place before this last change occurs. Evidence of cicatrization is, in rare instances, observed, when the disease has been of long duration. Ulceration does not attack all the patches containing the enlarged glands; for resolution sometimes takes place, or absorption of the matter they contained.

516. *e.* The *mesenteric glands* are very generally more or less changed, especially in connection with intestinal ulcerations. They are frequently only enlarged, sometimes softened, and occasionally both enlarged and indurated. In some instances, puriform matter may be traced in the sanious blood which they contain. They are usually only enlarged or indurated, or sometimes injected in fatal cases which have not been of long duration. M. CHOMEL gives the following as the results in the 42 cases examined by him:—Enlargement, with commencing softening and suppuration in 14 cases, dead from the seventh to the twenty-fifth day of the disease; marked softening in 12, dead from the tenth to the thirty-sixth day; redness, enlargement, and induration in 10, who died after the nineteenth day; slight enlargement, with a bluish, purplish, and blackish discolouration, in 3 cases, dead after the seventeenth day.

517. It would seem that the mesenteric glands

experience an analogous change to that of the follicles; that they become enlarged and softened about the same period as the follicles; and that, if the disease takes a favourable turn, they are gradually diminished, and assume their natural state. Suppuration is seldom observed in them, and ulceration never. The glands nearest the cæcum are those chiefly affected; and this is the part in which the follicles are most frequently and early diseased. M. CHOMEL does not think that ulceration of the follicles is the cause of the suppuration of the glands, as the latter may exist without the former.—I believe that softening of the mesenteric glands, with traces of puriform matter in them, may take place without any necessary dependence upon ulceration of the follicles.

518. *f.* The lesions observed in the other abdominal viscera are seldom such as materially to influence the termination of typhoid fevers. The *liver* is frequently more or less softened. M. LOUIS found this alteration in nearly one half of the fatal cases he examined. It is generally associated with softening of other organs, especially of the *spleen*. This viscus is enlarged in most of the fatal cases; in one half it is increased to about double its usual volume, or upwards. It is always also softened—sometimes very remarkably so. The alterations of these organs seem to have little or no influence upon the symptoms during life. The same may be said of the lesions of the mesenteric glands. Even the ulcerations found in the intestines have no determinate relation to the phenomena referrible to the digestive canal. Diarrhoea is not an uniform result of this lesion; and pain is seldom complained of unless at an early stage, or until the peritoneal tunic is perforated. The ochrey appearance of the stools, noticed by Dr. BRIGHT, cannot be depended upon as an indication of this alteration; and meteorismus, or a tympanitic state of the abdomen, although often attending it, indicates chiefly extreme depression of vital power, evinced especially in the weakened irritability or tonicity of the intestinal tunics, throughout the whole tube, rendering them incapable of resisting the accumulation of flatus. Many of the symptoms referred, by Continental writers, to organic lesions of the bowels, originating either in inflammation or irritation, are inseparable from the typhoid states of fever, and are the expression of the disease on the whole œconomy, rather than on this part of it in particular. That the affection of the digestive mucous surface and follicles is greater in some epidemics and countries than in others, and in large cities than in towns or country places, I am convinced from observation and the researches of modern pathologists. That it is more common in France, especially in Paris, than in England, is evident from the results of recent inquiries. Actual ulceration was found in *La Charité* by M. ANDRAL, in 92 cases out of 229 examinations and only in 16 out of 54, by Dr. TWEEDIE in the fever hospital. The proportions, although different, show the frequency and importance of the lesion, and the necessity of guarding against its occurrence in the course of the disease. But the above changes of the intestines and mesenteric glands are not confined to typhoid fevers. They often take place in other fevers, whether bilious or gastric, mucous, synochoid, &c., particularly in localities where the water is impure, and when these fevers

lapse into a putrid or typhoid state in their advanced stages, or when the fluids become deteriorated. Their frequent occurrence also in hectic is well known; and I believe that they would have been found still more frequently in all fevers, both continued and remittent, if the intestinal canal had been more generally inspected in that way in which only it can be said to be inspected, namely, by laying it open throughout its whole extent. That it has been very imperfectly examined in most epidemics, is evident, from the descriptions furnished of the morbid appearances, and from the circumstance of it having been very generally overlooked as late as the epidemics described by HILDENBRAND and others early in this century; and, although occasionally inspected by some of the writers upon the epidemic of Ireland, in 1817, 1818, and 1819, it was not until after the researches of BROUSSAIS, PETIT, BRETONNEAU, ANDRAL, and LOUIS, that attention has been generally directed to it. Making every allowance for the undue importance assigned to the lesions observed in this situation, the propriety of estimating them correctly, as to their origin and consequences, must be conceded.

519. *g.* The importance of the lesions observed in the *respiratory organs* has been alluded to. The *epiglottis* has been sometimes seen oedematous. M. CHOMEL found it ulcerated, with denudation of the cartilages, in three cases out of twenty which were carefully inspected. The *larynx*, especially its superior aperture, is occasionally also the seat of ulceration. When ulceration is observed in either of these situations, it often also exists in the *pharynx*, in which it seems often to have begun; and it is generally found to consist of several small but deep ulcers, commencing in the form of pustules filled with whitish purulent matter, but without any surrounding injection or inflammatory circle.—The *lungs* are often much diseased; but the alterations of them most frequently seen, occur only during the last days of life; and are referrible to the predominance of physical over the vital forces, as the disease approaches a fatal issue. But as congestion of the circulating fluids occurs in the more depending parts, the vital cohesion, particularly of the parenchymatous parts of the lungs, becomes diminished, giving rise to more or less marked *softening* of the engorged part. In less frequent instances it is not only a simple congestion from stasis of the fluids that is found, but also indications of pneumonia in the first or second degree. The pneumonia is sometimes confined to two or three lobules; in which case it may have passed into a suppurative state before death: in other instances it occupies a whole lobe, but without any signs of suppuration. Oedema, or even emphysema, of parts of the lungs, is also occasionally remarked. The *bronchi* are generally red, or of a livid red, or violet colour. The tint generally deepens in the small bronchi, and in the direction of the air-cells. They also contain some mucus.—M. CHOMEL gives the following as the state of the lungs in 42 cases:—Congestion, with or without softening, in 18; hepatisation in the first degree, in 3; hepatisation in the second degree on one side, in 2; lobular pneumonia, in 3; emphysema, in 2; oedema, in 2; effusion into the pleura, in 2; and the normal state, in 10.

520. *h.* The state of the *blood* varies much in

fatal cases of nervous, putrid, or typhus fever. Where the putrid, malignant, or septic characters have been most remarkable before death, the changes of the blood have been usually the greatest.—This fluid is commonly dark, black, diffu-ent; and but rarely in the state of fibrinous clots. In a few cases, the blood in the heart and large vessels assumes the form of black coagula, which are different from those observed in other acute diseases. This state is evidently owing to the absence, or great diminution, of fibrine. The presence of a gaseous fluid in the blood, especially in that of the veins, is also evident in some cases. I have observed this circumstance in death from other diseases, particularly if asphyxy was the mode in which the fatal event took place. (See art. BLOOD, § 110. *et seq.*)

521. *i.* The *heart* is often softened and somewhat discoloured. The *softening* of this organ varies from an almost unappreciable, to a most marked, degree. In some cases it is so great, that the fingers may be pushed through the parietes of the ventricles with ease. This diminution of cohesion is generally observed in cases where the changes in the blood, and softening of the liver and spleen, have been the most remarkable. *Flaccidity*, or a state of softness different from that just mentioned, is still more frequent. The flaccidity may exist without very manifest loss of the cohesion of the structure; but it is generally attended by some degree of the latter, and the softening may be great, and yet the flaccidity not very apparent, although this is rare.—The *colour* of the internal membrane varies in different cases, and even in the opposite sides of the heart in the same case. In some the membrane is red; in others dark, brown, or livid: it is often colourless, particularly when the heart is softened. It never presents inflammatory appearances, nor the changes immediately proceeding from the inflammatory state.—The researches of MM. TROUSSEAU, RIGOT (*Archives Génér. de Méd.* t. xii.—xiv.), and CHOMEL (*Clinique Méd.* p. 279.), show that the redness often found in the aorta, cavities of the heart, and large veins, in this class of fevers, is entirely owing to the tinging by, or to imbibition of, the colouring particles of the blood. Inflammation of the heart, or of its membranes, has not been observed in any case of these fevers.

522. *k.* The *external changes* observed after death most frequently commence a considerable time before this event. These consist chiefly of petechiæ, vibices, and blotches, varying as to size, situation, and depth of colour; and are to be ascribed to the extravasation of serum, coloured with red particles, or of blood itself, into the vascular layer of the skin. Gangrenous eschars, and sphacelus, are met with chiefly in parts pressed upon by the weight of the body, as the sacrum, shoulder blades, heels, and scalp of the occiput, or in those to which blisters, sinapisms, or other acrid substances have been applied. But these changes may occur in other situations, although rarely, and without these causes, as in the insides of the thighs; unusual pressure, or any other cause, either dissipating or exhausting the remaining vitality of the part, producing these effects. Phagedenic sores or ulcers, and enlargements of the absorbent glands, are also observed in rare instances. These sphacelating or spreading ulcers often commence in the form of pustules or vesicles,

which break, leaving a foul sore which rapidly spreads. Besides these, the usual consequences of erysipelas are sometimes observed, or the remains of exanthematous and miliary eruptions. Even emphysema has appeared shortly before, and has remained after death.

523. v. **PATHOLOGICAL CONCLUSIONS.**—The above exposition of the organic lesions, more especially proceeding from typhoid fevers, suggests some important considerations, relative not only to the nature, but also to the treatment, of these diseases. Few of these changes become apparent before the seventh day from the invasion when vascular action has passed into exhaustion, when organic nervous power and irritability are remarkably lowered, the circulating and secreted fluids are become morbid, and the powers of vital resistance in great measure overthrown. If inflammatory action should attack any part, either in this state, or even at an earlier stage, it will be very different as to its phenomena, its progress, and its results, from inflammation occurring primarily, or in a system whose vital and physical constituents are not materially deranged. It is the remarkable affection of these constituents by the causes of fever, and by the changes following more directly upon these causes, that imparts a similar character and termination to all the lesions now described. The depressed vital power of the extreme vessels, the lessened irritability of contractile parts, and the diminished vital cohesion of parenchymatous and other structures, heightened by the morbid state of the blood, are very frequently followed by gradual softening, infiltration, congestion, or effusion; and these often pass into disorganisation amounting even to sphacelation, or to sphacelating ulceration, even without the intervention of inflammatory action, or of any of its consequences. Owing to the intimate dependence of the states of the digestive canal, more especially of its internal surface, upon organic nervous influence, the former is involved, in a correlative manner, whenever the latter suffers. The tonic contractility of the muscular and serous coats of this canal is much diminished, the vital cohesion of its mucous membrane is weakened, the tonicity of the extreme vessels of this coat is lessened, and its functions of secretion impaired or otherwise changed. In this state, it is unable to resist the impressions made by morbid secretions passing over it. The alterations which had previously taken place in the organic nervous influence, in the functions of respiration, and in the blood, have conjointly given rise to diseased—usually acrid, or irritating, or septic—secretions from the liver, pancreas, and even also from the intestinal surface. When we find these secretions produce spreading or sphacelating sores, as they often do, in the protected cutaneous surface, we cannot be surprised at their occasioning analogous lesions in the more delicate mucous surface of the intestines, rendered still more delicate and susceptible of lesion by the previous changes just described. During the several days of the patient's life, from the commencement of these changes, or from the presence of morbid secretions in the intestinal canal, absorption will proceed on the digestive mucous surface; and, notwithstanding the amount of absorption may be very small, yet we cannot conceive it possible, that morbid secretions, either floating through the intestines, or collected

in the follicles, will pass through absorbent glands, or even into the vessels which run to them, without producing a material change in them. If these views be just, the inference that depressed organic nervous influence and irritability, a morbid state of the blood, and disorder of the secretions, are concerned especially in causing the changes of structure observed in the digestive canal, will be admitted; and, if admitted, it becomes the basis of a rational method of treatment. But these early pathological states induce also those organic lesions in typhoid fevers, affecting other internal organs, and even other external parts, and stamp them all with the same important characters—characters indicating both a common origin and a similar tendency, and pointing to the same principles of cure.

524. XXIV. **TREATMENT OF SYNOCHOID AND TYPHOID FEVERS.**—i. **TREATMENT OF SYNOCHOID FEVER.**—In this fever, as well as in all others in temperate climates, the *indications and circumstances* stated above (§ 123, 124.), as deserving of especial attention, should be strictly observed. The prevailing epidemic, and the changes that take place in its nature, or characteristic states of vital action, with its progress and with the season, should be carefully studied and made the basis of treatment. Some difficulty may occur at first in coming to just conclusions; but it will vanish with the extent of observation, especially when diligence has been used. The chief points to which the attention of the practitioner will be directed, are—the nature and concurrence of the causes, the extent to which they may have affected vital manifestations, the degree of excitement or vascular reaction in connection with nervous power, the state of the circulating and secreted fluids, and the nature and amount of local complications or determinations. The physician who has studied, in an intimate manner, the various phases of disordered vital manifestation, will have little difficulty in recognising the chief characteristics of fever under the ever shifting circumstances in which they present themselves, and in appropriating accordingly his method of cure.

525. A. The ancients observed carefully the spontaneous changes which take place in fever, and conduce to recovery (see art. *CRISIS*); and they were guided, in forming their indications of cure, by these changes, which they merely attempted to promote or to imitate. This mode of practice may be followed in synochoid fever more successfully, perhaps, than in any other. Yet it will be better to combine with it the more modern indication, of resorting to such means as may subdue the more urgent symptoms, and avert contingent danger. a. If the patient be seen as early as the *premonitory* and *invading* stages, the impending disease may be averted by the means advised above (§ 121, 122.)—more especially by *emetics*, warm *diaphoretics*, and the *vapour bath*. But when *excitement* has commenced, the treatment should be antiphlogistic. In this stage we should endeavour, by a careful examination of the symptoms, to ascertain the existence of local complications; and, having determined their absence, the question will then be as to having recourse to *bloodletting*. I have already considered this topic so fully (§ 128—139.) that nothing further need be here

advanced. If the nature of the prevailing epidemic, or the degree of reaction, require depletions, the earlier in this stage they are resorted to the better. But even then they require caution and discrimination. If the excitement be slight, and the patient neither robust nor plethoric, and more especially if the causes and circumstances connected with the origin of the disease be of a depressing nature, they will be better withheld.

526. *b.* The exhibition of *emetics* in the stage of excitement was advised by many of the ancients, and practised by some of the most recent writers, although objected to by others. The reason of this difference of opinion is very obvious. There are states, even of this stage, in which they will be of service, and others in which they will be injurious. When reaction is slight—when the patient is not plethoric, has not experienced full vomiting, and does not complain of pain or of tenderness in the epigastrium or hypochondria—then emetics may be exhibited. But if the excitement be great, with determination to the head; and if the patient have already vomited freely, and more especially if the symptoms just mentioned be present, they should not be prescribed. (See § 149.)

527. *c.* *Purgatives*, so much decried by BROUSSELS, and with some justice as respects several states of fever prevalent in France, are certainly of very great service in the common continued fever of this climate, when employed with a cautious discrimination. Early in this disease, calomel, either with or without James's powder, may be given at night, and a purgative draught in the morning. At a more advanced stage, calomel, or hydrargyrum cum cretâ, may be conjoined with rhubarb. If the stomach be too irritable to retain the more common purgatives, a full dose of calomel will generally be retained; but its action should be promoted by enemata (see F. 140. 144.). During the febrile excitement and when the bowels are sluggish, the stronger saline purgatives may be given in solution, in small doses and at short intervals, with refrigerants (F. 440, 441.). The remarks already offered upon this subject (§ 150, 151.) will guide the practitioner as to the choice of purgatives, and the extent to which they should be prescribed. In this fever, especially, it can never be injurious to give them to the extent of freely evacuating morbid accumulations in the bowels, and of promoting the alvine secretions and excretions. When the fæces are very offensive, greater mischief will accrue from allowing them to remain, even for a short time, in the bowels, than from too active measures in evacuating them.

528. *d.* The remarks that have been offered above respecting *refrigerants* (§ 139, 140.), *diaphoretics* (§ 152.), and *diuretics* (§ 153.), are entirely applicable to this form of fever.—The *cold affusion*, which formerly attracted so much more, and now so much less, attention than it deserves, is more appropriate in this than in any other disease. This practice, although resorted to by the ancients and in Eastern countries, was but little known in this until it was employed by WRIGHT and JACKSON. The work of Dr. CURRIE on the subject first brought it into fashion; but now it certainly has not fashion in its favour. When the excitement is fully developed, and the

heat of skin above the natural standard, when there is no sense of chilliness, and when the surface is hot and unperspirable, the cold affusion may be employed. Dr. CURRIE directed water of the temperature of from 40° to 60° or 70°, and preferred the hours from six to nine in the evening for its use. In cases of debility the *cool* or *tepid* affusion is more appropriate. I have resorted to cold affusion over the whole body, in several cases of fever, in a warm climate; but I was not induced by its effects to entertain a high opinion of it. The affusion of cold, cool, or tepid water on the head, when this part is prominently affected, and cold sponging the surface, are more beneficial, and admit of more general application. Dr. CURRIE believed that the general affusion had the effect of lowering the pulse and the morbid heat, of inducing perspiration and sleep, and of cutting short the fever. I have never seen it succeed unequivocally in producing the latter effects; but have remarked that the excitement returned shortly after its use. In the complication with disease of any of the thoracic or abdominal viscera, it should not be used (§ 141.).

529. *B. Of the Complications.*—*a.* Predominant affection of the head has received attention above (§ 165.). What I have there stated is applicable to this complication of common continued fever.—*Bloodletting* is especially requisite, but its amount, and the mode of performing it, should entirely depend upon the symptoms and the stage of the disease.—The *cold effusion* on the head, and *purgatives*, are the next in importance. When the cerebral affection has been preceded or attended by diarrhœa, purgatives should be prescribed with caution. Rhubarb with hydrargyrum cum cretâ, given so as to evacuate morbid matters, and promoted by suitable enemata (F. 140.), will be then sufficient. When *delirium* is the principal symptom, care should be taken to discriminate accurately the states of vascular action and of vital power. If it be unattended by increased heat of scalp, the pulse being very quick and soft, and the countenance sunk or pale, and especially if it have followed intestinal disorder, all lowering agents should be laid aside, and restoratives with opiates, and mild nourishment in small quantities, prescribed. When fever occurs in persons addicted to spirituous or other intoxicating liquors, the cerebral affection is apt to become very severe, and to be attended with delirium and often with tremor. In such cases depletions should be used with caution. If tremor, irritability, &c., appear, opium, with or without camphor, should be exhibited. In other respects, the means advised in the article DELIRIUM, according to the pathological states upon which it depends, will be here appropriate. I have repeatedly seen the cerebral symptoms greatly aggravated by the application of a *blister* to the scalp, at a too early stage of the disease. Blisters should be applied preferably on the nape, but never on the head unless there be profound coma, or low delirium with great exhaustion of vital power, as more fully shown in the articles COMA (§ 16.), and DELIRIUM (§ 19.).

530. *b.* The observations already made respecting the *pulmonary complications* (§ 160—163.) are mostly applicable to those occurring

in this form of fever. — *Bronchitis* is the most common affection, and requires the treatment above advised (§ 161, 162.). When the substance of the lungs, or the pleura, is implicated, vascular depletions ought to be early practised. But even in these cases, we should recollect, that bloodletting must be employed with greater caution than in inflammations occurring primarily and in healthy constitutions. It is in this fever and in its pulmonary complications especially, that antimonials may be given with greatest freedom. After depletions and antimonials have been carried as far as seems prudent, blisters, or other external derivatives, should be used. If the air-passages become loaded with mucus, antimony or ipecacuanha or sulphate of zinc may be given so as to excite full vomiting.

531. *c.* *Predominant affections of the digestive mucous surface* have already received attention; and the treatment there recommended (§ 155—159.), is quite appropriate in these complications of this form of fever. — In the *gastric state* of disorder, particularly when much pain and tenderness, with irritability, exist, local depletions should be early employed; and a full dose of calomel, given shortly afterwards, will generally allay what may remain of these symptoms. Enemata, also, will assist materially in producing this effect, and evacuate morbid matters from the bowels. Small, but often repeated, doses of hydrochlorate of ammonia, or of the nitrate of potash with the carbonate of soda; or camphor julep, with the solution of acetate of ammonia, and nitre or spirit of nitric ether; will afterwards be extremely beneficial. Even in this form of fever, but still more in the adynamic, we should be cautious not to be misled by the persistence of pain and tenderness at the epigastrium; or induced to prescribe too frequent or too large depletions with the view of overcoming these symptoms. They may never be removed by these means, however freely employed; for, notwithstanding the arguments of Broussais for their origin in inflammatory action, I believe that they depend more upon the altered state of the organic nervous sensibility, than upon increased vascular action in the stomach.

532. In the *enteric complication* the treatment will depend upon the stage of fever at which it appears, and the progress it may have itself made. — Local depletions, external derivatives, and the other means enumerated above (§ 156—159.), are generally necessary. If bloody or ochrey discharges are observed, especially late in the disease, the terebinthinate medicines, or the acetate of lead with opium, as advised by Dr. Bardsley, will be found the most efficient remedies. If the powers of the system become much reduced, gentle tonics, with the chlorates, as the infusion of valerian with the chlorate of potash, and paregoric elixir, will be of essential service. The following medicines will prove of great use in earlier stages of this complication, after local depletions, especially when aided by external rubefacients and derivatives. In slight cases, either of them may be given, according to circumstances; in the more urgent, both may be taken alternately, at intervals of three hours.

533. *ii.* *TREATMENT OF TYPHOID FEVERS.* — The treatment of this class of fevers is the most difficult in practical medicine. If the physician possess not just views as to the different and varying states of vital action, and as to their influence in producing organic lesion — if he be not enlightened as to physiological pathology, as well as to pathological anatomy — if his knowledge of the instruments of his art be not adequately varied and comprehensive — if his resources be not great and based on science — he administers to a patient in any of the forms of typhoid fever, with an equal chance of doing mischief, or of affording benefit; and he may as well adopt his plan of treatment from the “hazard of the die,” as to attempt to reason on the matter. It is better that the patient were left to the spontaneous efforts of nature, than that he should fall into the hands of such a practitioner. If we look back to the influence of theory and system in the treatment of these diseases; to the importance bestowed on names; and to the manner in which names have been confounded with, or substituted for, indefinite and varying entities; we shall not be at a loss to explain wherefore it has often been a matter of difficulty to decide, whether or not medical interference has proved beneficial or injurious. This is, however, not an opprobrium to our science; but a proof of its difficulties, and of the ill-founded pretensions of many of its professors and teachers. In our own days, we have seen pretensions to which ignorance gave confidence, and for which professional cant procured currency, obtain a credence which now seems surprising, and produce results which the adequately informed always anticipated. We have witnessed the promulgation of doctrines, and of modes of practice, warranted neither by an acquaintance with vital actions, nor by a knowledge of, or regard to, facts, lead to the most serious consequences; and have remarked, moreover, the power they obtained over those who were either unwilling or unable to inquire into their truth. But we have also seen, in the brief space of two or three years, the illusion vanish before the increasing and spreading lights of pathological and practical knowledge.

534. The difficulties attendant upon the treatment of this class of fevers depend chiefly upon the varying states of vital action in their course; the modifications and complications they present in different circumstances and epidemics; and the inadequate means of discrimination in our power, between the changes induced by treatment and those taking place spontaneously. — It is not also from the effects produced upon a few detached cases, that we can judge sufficiently of the efficacy of certain remedies; but from the results in a number — from the rate of mortality in various circumstances, and in different epidemics. Whatever may have been the method advised by writers — too many of whom have written from motives wide from those by which alone they ought to have been actuated — we shall find, upon close inquiry, that the general mortality has been such as to demonstrate its little efficacy, or to show the small superiority possessed by it over others.

535. The ancients observed the changes which

take place in the course of fevers with great attention, attributed recovery to the critical evacuations which frequently occurred in their advanced stages, and did not attempt to interfere with the efforts of nature as long as the disease pursued a simple and mild course; but interposed in order to accelerate and replace evacuations, when they did not occur after a certain period, or were interrupted by any circumstance. The chief fallacy in this doctrine is, that the evacuation, when it occurred, was mistaken for the cause of the amendment, instead of being viewed as the effect, and as one of the signs by which this change is often indicated.

536. The physicians who, in modern times, attributed an important part to putridity of the humours, recognised merely a portion of the mischief, and that often the most remote and contingent, and mistook, in great measure, both its origin and nature. They had recourse to camphor, bark, musk, and various preparations, both vegetable and mineral, possessing antiseptic properties; and, if they had employed them in appropriate periods and states of the disease, the benefit derived from them would have been much less equivocal. But, mistaking the origin of the phenomena usually called putrid, they frequently prescribed these medicines improperly; and whilst endeavouring by an early exhibition of them to prevent putridity, they actually often accelerated or favoured its occurrence.

537. A nearly similar mode of treatment was advised by BROWN, and his once numerous followers on the Continent; but it was based upon a different doctrine—upon the predominance of the asthenic diathesis and its consequences. Although wine, opium, tonics, and stimulants, were recommended by them, in various forms and combinations, with advantage, in certain states of typhoid fevers, particularly in the latter stages; yet the evils resulting from an early recourse to them were also sufficiently evident, and at last became manifest even to the disciples of this school. That this practice, and the modifications introduced by its partisans, did not prove so injurious in the treatment of fever, especially on the Continent, as may be supposed, is accounted for by the circumstance, that depressed vital power, with septic changes in the fluids in the last stages, characterised the much larger proportion of fevers prevalent for several years after its promulgation. But the appearance of exanthematic typhus in the north of Italy, at the close of the last century, opened the eyes of RAZORI to the impropriety of having recourse to stimulants in its treatment, and laid the foundation for the doctrine and practice of *contra-stimulus*. The general character of the petechial fevers prevalent about the commencement of the present century in Italy and Germany, was such as I have delineated in the section on typhus (§ 485.), with more or less of inflammatory or irritative action in the stage of excitement; the exanthematous eruption in this stage being frequently mistaken for petechiæ, and the appearance of these, and of other adynamic symptoms, being favoured by the vascular reaction which preceded them.

538. The administration of the *potassis tartrate* of antimony in large doses, was the principal treatment employed by RAZORI. When the patient was young and robust, and the disease had not reached

the acme of excitement, he directed a moderate bloodletting at the outset, and immediately afterwards, four, six, eight, ten, or twelve grains of tartar emetic, or even more, in solution. He prescribed this medicine in smaller doses subsequently, or substituted for it the *kermes mineral*, conjoined with nitre, and in doses of one grain, or of a grain and a half, every half hour, or hour, or every two hours, according to the degree of vascular excitement. He often gave the tartar emetic and kermes alternately. RAZORI also employed purgatives, particularly when the antimony did not act sufficiently upon the bowels; preferring neutral salts, manna, and tamarinds, in large doses, and administering them, in other cases, in enemata. He enforced a cooling regimen and severe diet, and allowed only refrigerant beverages. The success of this treatment is stated to have been great; and its propriety, as well as success, may be admitted, when employed in an epidemic characterised by high vascular excitement at its commencement, and when adopted sufficiently early after reaction has taken place, and in previously healthy persons. But in other states of typhoid fever, and in the latter stages especially, the large doses of antimony here advised appear not, *a priori*, to be suitable means. It should, however, be admitted, that the exhibition of the potassis tartrate of antimony in the advanced stages of this fever has never been satisfactorily tried, either in this country or in France and Germany. That it may be found not so inappropriate as generally considered, is an inference which the trials made of it, very recently by Dr. GRAVES, of Dublin, fully warrant.

539. The pathological tenets lately prevalent in France have, as M. CIMONEL states, prevented the treatment of RAZORI from being adopted, or even tried in that country. The doctrine of BROUSSAIS was opposed to this, and every other means that seemed to its supporters likely to aggravate the inflammatory action of the digestive mucous surface, which they supposed to be the cause of all fevers. If we examine the practical tenets of this school, we shall find more than one postulatam assumed as fully established, although admitting not only of doubt, but even of disapproval. That fever does not depend upon this lesion, although predominant morbid action in the digestive canal may appear in many cases, and in some fevers more frequently than in others, has been already shown. And, granting that this morbid action is attended by vascular injection of the mucous membrane, it still remains to be proved that it is the same kind of affection as inflammation. That it is not the same as primary and sthenic inflammation, its phenomena and results, as well as the *juvantia* and *lædencia*, sufficiently prove. Even granting the doctrine of BROUSSAIS in its fullest range, it still remains to be demonstrated, that the treatment advised is that which is the most beneficial, or the most appropriate, in the numerous and varying morbid conditions which fevers assume; and it, moreover should be shown, that the means which the espousers of this doctrine reprobate, are one whit more prejudicial than those which they laud. In a class of diseases so varying, and even opposite, as to their pathological states, as fevers are, not only in their different forms, but also in the same case at different stages, the success of various

remedies cannot be predicated from doctrinal tenets. However ingenious the theory, and close the reasoning, by which we are led to practical inferences, careful experiment and repeated observation are necessary to test the character of any method of cure; and even were we to adopt the views of BROUSSAIS, to these tests we ought to resort before we should decide between the efficacy of gum-water and leeches on the one hand, and that of antimony and purgatives on the other; or, indeed, respecting the propriety of any remedy whatever.

540. The pathological views of HOFFMANN, and the modifications of them by SAUVAGES and CULLEN, although entirely based upon solidism, were favourable to rational modes of practice. These views, in the varying explanations of them furnished by HEBERDEN, FORDYCE, and others, have very generally guided practitioners in this country in the treatment of typhoid fevers, until DR. HAMILTON introduced a modification of the usual practice, or induced them to have a more frequent recourse to purgatives than had previously been ventured upon. That these remedies, especially when judiciously selected and combined, do not produce the mischievous effects in typhus which BROUSSAIS supposes them to produce, even when given in cases the most favourable to his views, I am convinced by experience, and many of his disciples are at last opening their eyes to the fact. MM. BRETONEAU, ANDRAL, and others, more or less partial favourers of his doctrine, have recently so far discarded the practical tenets of their school, as to venture on the exhibition of these medicines;³ and, as M. CHOMEL justly remarks, have found that the dread of them so long entertained is unjust, and that they may be employed early in many cases of typhus with great benefit. Where, however, there is reason to suspect the existence, or even the commencement, of ulceration, the impropriety of having recourse to them, unless with the circumspection and in the manner hereafter to be mentioned, cannot be doubted. But ulceration seldom occurs before the twelfth day of the disease; and if they have been judiciously employed previously, I believe that it will very rarely take place either then or at a later period.

541. The humoral pathology, although superseeded very generally by solidism, since the days of HOFFMAN, still continued to be partially adopted by some practitioners in different parts of the Continent. It has been lately revived in a too exclusive manner in this country. Amongst those who have espoused views of this kind may be mentioned DR. STOKER, DR. CLANNY, and, still more recently, DR. STEVENS — each of whom has endeavoured to establish the early predominance of morbid states of the blood. These views have been already partially discussed; and I have now nothing further to add respecting them, than that the changes of the blood for which DR. STOKER argues, are those which have been above stated (§ 520.), and which refer merely to its external appearances. DR. CLANNY insists chiefly on the diminution in typhus of the carbonic acid, which he supposes the blood to contain in health. He recommends the use of fluids, containing or evolving this gas, as effervescing draughts, Seltzer water, &c. M. CHOMEL states, that he gave this practice a trial in the Hôtel Dieu during two

years; and that, although the cases in which he employed it were not numerous, they satisfied him that it did not influence the usual results, and that he preferred, therefore, to try other means, the inefficacy of which had not been so fully shown. Of the treatment of DR. STEVENS, in respect of this class of fevers, I entertain similar opinions to those expressed above (§ 387.). In two cases of low nervous fever to which I was lately called, at a period, however, too late to expect benefit from any treatment, I prescribed the remedies this writer has advised, but without any effect.

542. If the rational method of treatment, or that which is modified according to the form, state, or stage of the disease, is not much more successful than that which is dictated in the spirit of system or of empiricism, it has at least this to recommend it, — that it brings the results of science to bear upon existing pathological states, both vital and structural. Although not admitting so readily of the usual tests of success as more empirical methods, the experienced physician will readily form a tolerably accurate idea of the circumstances, either promoting or preventing favourable results. He will make due allowances for the forms and periods of the disease, the characters of the epidemic, the influence of season, and for the numerous circumstances appertaining to individual cases; and he will at once perceive that the means that are beneficial in one epidemic, or in one form of fever, or in certain cases, will be most injurious in others. In the present state of our knowledge, the rational method of cure is that which is most appropriate to the different varieties and stages of fever. According to it, indications or intentions are derived from a due estimate of existing symptoms and signs, and of the pathological conditions evinced by them. Whilst it comprises every method of cure, and all kinds of means, it adapts them to the states of the disease and of the patient. The judicious physician employs, according to circumstances, remedies the most opposite; and, in different cases, or in different periods of the same case, he has recourse to sedatives, to refrigerants, to evacuants, to tonics, to astringents, to stimulants, or to antiseptics. He neglects no means, but adopts none exclusively; and while interpreting the value of symptoms, and inferring the morbid states producing them, he endeavours to select and to combine the medicines, whose known operations are such as are most likely to remove these states, or to prevent the accession of others usually supervening in the course of the disease, and increasing its danger. — I will now proceed to consider — 1st, The treatment appropriate to the different stages of typhoid fever; — 2dly, The modifications required by its different forms and complications; — and 3dly, The means recommended in a special manner, and the circumstances or states of the disease in which they may afford benefit.

543. A. The Treatment appropriate to the stages. — a. In the premonitory stage, and whilst that of invasion is not fully formed, the future fever may be checked or prevented by the shower bath, followed by frictions of the surface; by an emetic, or by a warm stomachic purgative; or by a warm or vapour bath; or by all these following in succession; and in some cases, also, by warm diluents or diaphoretics; but this result cannot

be depended upon.—*b.* When the *stage of invasion* is pronounced, bleeding, hot stimulants, &c. are hurtful, or even dangerous. Tepid and warm diluents, and the warmth of bed, are the most suitable means. If vomiting accompany this stage, it may be increased by tepid and emollient diluents. If nausea only be complained of, and if there be little pain, tenderness, or tension, in the hypochondria and epigastrium, an emetic may be given, and its action promoted by these means.—This treatment will generally shorten the chills, &c. characterising this period, and favour a relaxation of the surface, or the occurrence of moderate reaction.

544. *c.* In the *stage of excitement* the treatment must altogether depend upon the degree in which reaction is developed, and the manner in which the brain, the lungs, or the digestive canal, appears to suffer. If the fever does not present, early in this state, the characters of low nervous fever, to their full extent, or those of an adynamic or of a putrid or septic kind, then a small or moderate *bloodletting* may be prescribed; but the effects at the time of the operation should be carefully observed. If the patient be young or robust, previously healthy and well fed, then a more copious depletion may be practised, if he be seen early. Even in the lower states of this fever, if any of the viscera just named be prominently affected, a *local depletion*, either by leeches or by cupping, may be employed. But if the period of excitement be far advanced; if the fever be simple or mild; if it have passed the tenth day; and if it be the true or exanthematic typhus, unattended by inflammatory associations; bloodletting will seldom be of service, and it may interrupt the regular and favourable course of the disease, particularly the latter form of it. In a large number of cases, in which M. Louis states bloodletting to have been tried, and in which it appears to have been indicated, the advantage procured by it seems to have been slight; but sufficient to increase, to a small amount, the proportion of recoveries, and to diminish the duration of the disease.—*Emetics* have been advised also in this stage; and, in cases where the chills return on successive days, or frequently alternate with flushes, I believe that they will be found of service. HILDENBRAND directs them in the first, second, or third day, or even later; having premised a bloodletting in the cases indicating it; and prefers a large dose of ipecacuanha, with a grain of tartar emetic.—Next to emetics, *purgatives* are of advantage. At an early period, or before the eighth or ninth day, a full dose of calomel, either alone or with rhubarb, may be given; or jalap, with cream of tartar; and their action promoted by moderate doses of the neutral salts, or by manna, tamarinds, &c., according to circumstances. These clear away morbid secretions and mucous sordes, from the digestive surface; which, if allowed to remain, would favour the occurrence of the morbid changes in the intestines. If, however, the bowels have been much relaxed, and still continue so, it will be preferable to give an occasional dose of hydrargyrum cum cretâ, with rhubarb, and ipecacuanha, which will promote a healthy state of the mucous surface, and facilitate the evacuation of morbid secretions. If the bowels be only gently open, the circumstance is favourable; but an inordinate action of them must be

moderated by the above medicine, or by others hereafter to be mentioned, lest intestinal ulceration and perforation be the ultimate result. At the same time, care should be taken not to produce a sudden change or constipation, otherwise the cerebral or nervous symptoms will generally be much aggravated, and a tendency to effusion on the brain be produced.—*Diaphoretics*, suitable to the state of the symptoms, either variously combined, or associated with diuretics, may be given from time to time. Of these, the more refrigerant, with small doses of camphor, will be most serviceable; and either some one of those in the Appendix (F. 431. 436. 440. 818. 865.), or the following, may be prescribed:—

No. 225. R̄ Camphoræ rasæ gr. ss.—j.; Potassæ Nitrat. gr. iij.; Pulv. Acaciæ gr. ij.; Mucilag. Acaciæ q. s. M. Fiat Pilulæ ij. quartis horis sumende.

No. 226. R̄ Mist. Camphoræ ʒj.; Liq. Ammonia Acetatis ʒj.—ij.; Ammonia Hydrochloratis gr. iv.; Syrupi Limonis ʒj. M. Fiat Haustus, quartâ quaque horâ capiendus; vel interdum, secundis horis, pilulæ et haustus, alternis vicibus, sumantur.

545. *d.* In the *nervous stage* the debility is more real; irritability is more exhausted, and the sensorium more severely and uniformly affected. The functions of the skin, and frequently those of the bowels, are also more disturbed than before. The *indications* are to support or stimulate the system, according to the forms the disease assumes.—*Blisters* may be employed in this stage—seldom before. They favourably impress the nervous system, check the tendency to diarrhoea and affection of the intestinal mucous surface, and render the skin more perspirable. They are most serviceable at the commencement of this stage; and are best applied on the nape of the neck, behind both ears, or on the calves of the leg.—*Camphor* is now one of the best remedies that can be exhibited. Whilst it promotes nervous power, it relaxes the skin, and does not increase inflammatory action, but rather tends to allay it, particularly the nervous and cachectic forms of it, which alone can exist in this disease. It should be given in larger doses in this stage, more especially of the malignant or putrid form. From twelve to twenty grains may be exhibited in the twenty-four hours. HILDENBRAND advises, in the latter part of this stage, medium doses of camphor; or one grain every two hours, with an infusion of *arnica* and *angelica* root. He considers that these lessen the stupor, giddiness, and delirium; act favourably on the skin; and prevent the tendency to diarrhoea.—*Emetics* are sometimes beneficial in this stage, when they have been neglected in the previous one, or contra-indicated.—*Purgatives* are of service only when the bowels require assistance. They should be given with the intention of evacuating morbid matters, of preventing the injurious impression made by such matters upon the intestinal mucous surface, and of promoting a healthy action of the abdominal emunctories. Hydrargyrum cum cretâ, and rhubarb, and the infusion of the latter with the milder saline substances, in a state of effervescence, are the most appropriate. These preserve the tone of the digestive mucous surface, whilst they enable it to throw off faecal collections. Their action may be occasionally promoted by emollient and gently laxative enemata. I doubt much the propriety of exhibiting *calomel*, or any of the drastic purgatives, in this stage; and I believe that the more active neutral salts exhaust the strength

and produce watery stools, in this period, particularly if they be exhibited in any quantity. It is in the common, or synchoid, form of fever, or at the commencement of this, that they may be employed. In the latter stages of low fevers, calomel and cathartics are apt to increase the intestinal symptoms, or to determine an irritative action of the bowels, liable to terminate in the lesions already noticed.

546. *e.* When the disease has reached its *acme*, or is approaching the fourteenth day, the treatment should very much depend upon the predominant symptoms, upon what has been already done, and on the effects observed. — If no unfavourable symptoms are present, mild saline *diaphoretics*, as camphor mixture, with liquor ammonia acetatis, &c., or the former with the alkaline bi-carbonates, and citric acid, or lemon juice, in effervescence, and mild demulcent diluents, are all that are required. The chief intention at this stage is to favour a genial perspiration. The temperature of both medicines and drinks should not be lower than tepid. If the disease is complicated, particularly at this period, or is proceeding irregularly, the treatment must be varied, as will be hereafter shown. If a crisis take place, or the more urgent symptoms gradually subside, the means should vary with the degree of vital depression evinced. Both tonics and stimulants should at first be mild, in moderate doses, and suited to the state of the pulse, and of the skin and bowels. At first, a cold infusion of *cinchona*, or the decoction, may be given, with the solution of the acetate of ammonia, or with either of the alkaline bi-carbonates and citric acid, in effervescence. The infusion of *valerian* may also be substituted for the *cinchona*, and given as directed above. — The *regimen*, *diet*, and *convalescence*, should be managed with strict reference to the forms and complications of individual cases, and as will be hereafter shown.

547. *B. The Treatment of the Varieties and Complications of Typhoid Fever.*—*a.* In the simple *typhoid*, or *nervous fever*, when it commences as described above (§ 459.), the period of excitement being characterised by little or slight reaction, *bloodletting* is seldom beneficial; or local bleeding, in a situation indicated by the prominent affection, will only be required. If the pulse be very rapid, or soft, and open; if the prostration be great, and the tongue assume a dark colour; and particularly if this state exist at the commencement of the disease; vascular depletions will be injurious. The indications enumerated above (§ 132, 133.) will further serve to point out when they may, or may not, be resorted to. — An *emetic* is always of service, particularly if there be nausea; and if vomiting be spontaneous it should be moderately assisted, as already advised. — The bowels should be evacuated early in the disease by mild *purgatives*. Those already mentioned are the most appropriate, or fresh castor oil may be used. They may be repeated occasionally, with the views I have stated, but with due caution, lest they induce too great exhaustion, or favour the supervention of intestinal disorder. — Whilst the heat of skin continues, *tepid* or *cold sponging* the surface is grateful to the patient, diminishes the restlessness, and favours the operation of *diaphoretics* during the state. — If diaphoresis occur it should be promoted by mild, tepid *diluents*, either simple or medicated, in the manner about

to be noticed. If copious perspirations occur, especially about the acme of the disease, or at a critical time, they should not be arrested, unless they increase the exhaustion, or are attended by signs of septic deliquescence. — In the *nervous stage* the treatment directed above should be employed (§ 545.).

548. *a. Prominent affection or consecutive inflammation of the respiratory organs*, in the nervous form of typhoid fever, requires the utmost discrimination on the part of the practitioner, for its successful treatment. The subject has been admirably elucidated by Dr. STOKES, in his truly excellent published lectures on fever. The chest should be carefully examined by the stethoscope, in order to ascertain, as accurately as possible, the state of pulmonary disorder, and to determine whether the symptoms referred to this organ be symptomatic, or dependent upon inflammatory action or active congestion. The able pathologist just mentioned remarks that, when the bronchial surface is chiefly affected, there is much more lividity of the countenance, than when a portion of the substance of the lungs is diseased. This symptom will generally verify the reports of auscultation. But the treatment will entirely depend upon the nature of the bronchial affection. If the dyspnoea and other pulmonary symptoms depend upon inflammatory irritation, rather than upon increased secretion from the mucous surface; if there be heat of skin, more or less vascular reaction, and if the patient be young and robust; *bleeding*, general or local, will be necessary, according to the severity of the symptoms and stage of the disease. If, however, these symptoms depend chiefly upon a copious secretion from the bronchial surface, as will be shown by the stethoscope, bleeding will be most injurious, and very decided means of an opposite nature will be requisite, in order to prevent contingent asphyxy. In this latter case extensive counter-irritation, the *mistura ammoniaca*, or the *decoctum senegæ* with camphor, ammonia, the *unctura camphoræ composita*, or other stimulating expectorants, must be resorted to, according to the urgency of the case, particularly if lividity of the face exist. When the strength is very much reduced *wine* will also be necessary, with light nourishment. The temperature of the surface should be kept up. Dr. STOKES very properly directs the patient to be enveloped in soft flannel. When the bronchial affection is more strictly inflammatory, and the secretion does not interrupt materially the functions of the lungs, antimonials may follow the bleeding. But in either case, if the symptoms referred to this organ, particularly the dyspnoea, or the cough, become urgent, and be attended by the tracheal rattle, an *emetic* of ipecacuanha, or of sulphate of zinc, should be immediately exhibited. In this state Dr. GRAVES, whose extensive resources, in matters of difficulty, I have had frequent occasion to notice, has tried the application of *moxas* in the course of the eighth pair of nerves, and the use of the sulphate of quinine and opium, in enemata; these latter exerting a powerful influence, in his opinion, in lessening excessive secretion from the bronchial surface. — If the substance of the *lungs* be affected, a single moderate bloodletting, or local depletions, may be prescribed, if the patient be robust and the disease not far advanced. If the bowels be not

materially disordered, antimonials may afterwards be given; but they should be combined with anodynes. Ipecacuanha, with calomel or camphor, and opium, or extract of poppy, is, perhaps, preferable in most cases.—*Diaphoretics* in frequent doses are always of service, and may be conjoined with diuretics. After depletions have been carried sufficiently far, or if the lungs are affected very late in the disease, *blisters*, *sinapisms*, or the *warm terebinthinated embrocation*, placed on the chest, and camphor, ammonia, ipecacuanha, or other expectorants, with hyoscyamus, or extract of poppy, are the principal means we possess. When in this complication the skin is cool and pale, the pulse very weak and small, and the features collapsed, the warm expectorants, as polygala, ammoniacum, ammonia, camphor, the stimulating tonics, and wine, should be given, according to the peculiarities of the case.

549. *β. Predominant affection of the intestinal mucous surface* should be treated by means similar to those advised in this complication of synochus; and the more especially, as the latter fever, when thus characterised, either passes into, or is very nearly allied to, the typhoid form. In the early stages of this complication a combination of small doses of hydrargyrum cum cretâ, rhubarb, and Dover's powder, with compound cretaceous powder, given every three or four hours, is generally of service. If the constitutional symptoms will permit, and if this affection appear at an early period of the fever, a local depletion should be premised, and a blister or sinapism be afterwards placed upon the abdomen. The terebinthinated epithem, applied sufficiently hot, and covered so as to prevent evaporation, if properly managed, is the most efficacious means—more particularly if the abdomen be tense, tender, or tympanitic. In this latter state, an injection with assafoetida, or with the extract of rue, or with from two drachms to half an ounce of spirits of turpentine in addition, will give great relief.

550. In a far advanced stage *diarrhœa*, especially if attended by tension, pain, or flatulent distension of the abdomen, requires great attention. If the medicines just recommended prove not of service, the *chlorurets*, particularly the chloruret of lime, may be given, with camphor, and extract of poppies, &c. Mucilaginous injections, containing syrup of poppies, or laudanum, or compound tincture of camphor, may also be administered, and a rubefacient epithem placed over the abdomen.—If *hæmorrhage* from the bowels occur, it may be ascribed chiefly to exudation from the softened mucous surface, as shown by the post mortem appearances; and *acetate of lead* with opium, or acetate of morphia, or extract of poppy, should be exhibited, either in the form of pill, or with the pyroligneous acetic acid, in strong camphor julep. The lead has been recommended, in these cases, by Drs. BARDESLEY, GRAVES, and STOKES. I have resorted to it in these several combinations, and have given it in two or three instances with kreasote.—I have likewise employed, by the mouth, and in enemata, the spirits of turpentine, which generally proves the most active remedy of any in such circumstances. In some hopeless cases it has succeeded contrary to expectations. In one, however, that recently occurred to me, although it arrested the hæmorrhage for a time, there was a

return which carried off the patient. If the disease be far advanced, or the powers of life much reduced, the turpentine should be given in small or moderate doses, and its effects carefully watched. I have also prescribed it in conjunction with kreasote, the acetate of lead and aromatics, in similar circumstances.

551. *γ. Prominent affection of the brain* may arise in the course of typhoid fever, either from congestion within the head, or from the depressed state of nervous power, unconnected with inflammatory action, or even with vascular determination. This circumstance, long believed by pathologists, has been fully confirmed by M. LOUIS, who found, that the presence or absence of delirium has little or no connection with perceptible organic lesion of the brain. If, however, there be increased heat or severe pain of the head, spastic contractions of some muscles, flushed face, injected eyes, or other indications of active disorder of the cerebral circulation, particularly in the stage of reaction, the hair should be removed, and local depletion resorted to. The head ought to be kept cool, by cold sponging, or lotions. If delirium be attended by these symptoms, the same means are required; and, if it be, at the same time, low, insensible, or muttering, a blister should be applied to the neck and nape, or behind the ears, or to the calves of the legs, or a sinapism may be substituted in the latter situation. Whenever the affection of the head is connected with increased determination to it, especially in an early stage, stimulating antispasmodics, as ammonia, musk, or camphor in large doses, cannot be of service, and may be injurious. The last of these, however, may be used in small doses with nitre, and it may be increased according to the degree of stupor, and coolness of the scalp. If the delirium depend upon exhausted nervous power—if it be attended by stupor; by a weak, soft and very quick, or somewhat slow pulse; by a moist skin, or copious perspiration; or by extreme prostration, particularly after the eighth or tenth day, or in the nervous stage; camphor, in doses of from one to three or four grains every two, three, or four hours; or the preparations of *valerian*, or of *serpentaria*, or of *arnica*, or *ammonia*, or of *ether*, or *wine*, or *opium*, may be severally employed as circumstances will suggest. In other respects, the treatment of this state, and of sopor and coma, its frequent attendants and sequents, should be directed, as explained in the articles *COMA* (§ 16. 19.), and *DELIRIUM* (§ 16, 17.).—*Retention of urine* is very apt to occur in this state; therefore, in it especially, but also in all others, attention ought to be paid to the circumstance. If an undue accumulation of water in the bladder be detected upon examining the hypogastrium, it should be immediately drawn off.

552. *δ. In the most severe form of nervous fever* (§ 461.), bloodletting is seldom of service, unless at the commencement of reaction, or from the vicinity of the most affected organ. When the skin is very hot, *tepid sponging*, *diaphoretics*, *external derivatives*, and *emollient diluents*, with *nitre*, or small doses of the *hydro-chlorate of ammonia*, are the most appropriate. The infusion of *valerian* may be given as the disease passes into the nervous stage, either with the *compound tincture*, or with camphor, and *hydro-chloric ether*, or other

stimulants. — HILDENBRAND advises the *arnica montana* with camphor, in this state. — If exhaustion increase, and coma come on, these medicines, or others of a similar kind, may be prescribed in larger doses, or at shorter intervals; and a blister applied to the vertex, or occiput, or to the nape; or a large sinapism to the epigastrium, or insides of the legs. LALLEMAND and MACKINTOSH have adduced instances of benefit, in the comatose state, from pouring boiling water on the lower extremities. *Musk*, the *ethers*, preparations of *cinchona*, or any of the stimulants already mentioned, may likewise be tried, in various combinations, in this stage; or an infusion of *green tea* may be given in the usual manner.

553. *c.* If the disease be sudden in its attack, or *apoplectic*, care should be taken to ascertain whether or not this character arise from weakened nervous energy of the brain, or from vascular congestion. When a pale, collapsed countenance and eyes, weak and small pulsation of the carotids, and coolness of the scalp, indicate the former, restoratives will be necessary. But, when there are increased temperature of the head, and excited action of the carotids, although the countenance be pale, a small or moderate bloodletting, local or general, or even a cautious repetition of it, in young or robust persons, will generally be required. — The same remarks equally apply to the occurrence of *paralysis*. If the paralysis appear at an advanced stage, even local depletions may be injurious. In this case, we must trust chiefly to blisters and other external derivatives, and to the means already stated (§ 551.).

554. If, in the early stage of this, or, indeed, of any other form of typhoid fever, the thirst be urgent and attended by vomiting, desire of cold fluids, and heat of skin, stimulants are generally injurious. If tenderness of the epigastrium accompany these, inflammatory irritation, or erythema, of the gastro-intestinal mucous surface should be inferred. In this case *leeches* ought to be applied; and cold or iced drinks and saline medicines, particularly the nitrate of potash, or the hydro-chlorate of ammonia, frequently exhibited. A combination of camphor mixture, the solution of the acetate of ammonia, nitrate of potash, and spirits of nitric ether, will generally be serviceable in these circumstances. Effervescing draughts are productive of little benefit, as the extrication of fixed air distends the stomach, and either causes it to react upon, and throw off, its contents, or gives rise to much distress and pain. If irritability of the stomach still continue, a large blister may be applied over the epigastrium. Dr. STOKES advises, in the more obstinate cases, the raw surface to be sprinkled with a small quantity of the acetate of morphia. I have rarely found the warm turpentine embrocation fail of removing this state of disorder, when properly employed.

555. *ç.* When *singultus* occurs in the stage of reaction, it is generally connected with the foregoing state of the stomach, and particularly with irritation about the cardiac orifice. In this state, the treatment just advised is the most appropriate. When it appears in the nervous period, or later, it depends upon exhausted nervous energy; and requires stimulants, antispasmodics, and anodynes. Camphor, ammonia, the ethers, musk, valerian, opium, and their preparations, variously combined, are the most serviceable.

556. *η.* *Diarrhoea* is one of the most frequent precursors of disease of the intestinal mucous follicles; yet should it not be rashly interfered with, and still less abruptly arrested, particularly when it occur early, or at a critical period. I have imputed the affection of the intestinal mucous surface in great part to the morbid condition of the blood; this surface being one of the channels by which effete, or injurious materials, pass out of the circulation during the course of fever. It is evident, therefore, that if we shut it up without opening others, the alterations of the blood will increase, and occasion serious organic changes, and ultimately a fatal issue. The most rational procedure, when diarrhoea is an early complication, is not to interfere with it, unless it become severe, or continue long; and then it should be moderated rather than arrested, and by such means as will increase the depurating functions of the skin, the kidneys, and liver, and remove the irritation excited in the digestive mucous surface and follicles. The remedies most likely to produce these effects, are actually those which have been found most serviceable in this state of disease. Hydrargyrum cum creta, compound ipecacuanha powder, camphor, nitre, mild anodynes, variously combined with demulcents, emollients, and diluents, are the most generally of service. In more advanced states of this complication, and in later stages of fever, those medicines which have been already noticed (§ 156.), as well as some about to be mentioned, may be resorted to. — When the pulse is small, very frequent, and weak, and the strength exhausted, diarrhoea must then be arrested, otherwise it will speedily terminate life. Astringents, opiates, absorbents, restoratives, wine, &c., are all requisite in this case.

557. *θ.* *Tympanitic distension* of the abdomen may occur early in this fever, and be attended by thirst, by a desire of warm diluents, by tenderness on pressure, particularly in the lower part of the right side of the abdomen, and by diarrhoea. When these symptoms are present, disease of the intestinal mucous follicles may be inferred. In this case a number of leeches, according to the strength of the patient and stage of the fever, should be applied, and followed by the warm turpentine embrocation on the abdomen. If tympanitis and diarrhoea appear late in the disease — particularly if the stools be foul, watery, or mucous — ulceration of the intestinal surface should be dreaded, and the means already advised (§ 156.) should be resorted to; or the chlorurets given in the infusion of valerian, or in emollient vehicles, with camphor, anodynes, &c. From one or two to four or five drachms of spirits of turpentine may be prescribed once or twice, or even oftener in some cases, in a suitable vehicle, if these fail; or this substance or assafoetida, or extract of rue, with some anodyne, may also be administered in mucilaginous enemata from time to time. In most cases of flatulent distension of the intestines, there is great disposition to ulceration of the aggregated mucous follicles — if, indeed, it has not already commenced and both morbid conditions are greatly aggravated by the continuance of the flatulent state. The *intention*, therefore, is to procure the discharge of flatus, by means which may at the same time sheath and soothe the irritable mucous

surface, and restore the lost tone of the capillaries of the diseased part; and, whatever operates in this way, will be productive of benefit. It is only by a judicious combination of agents, that this effect can be attained; and those just mentioned seem the most efficient, especially when the skin is cool, the pulse feeble, and the prostration extreme; and, in this state, the more energetic stimulants and tonics, or wine, or opium, may also be employed, according to the peculiarities of the case. (See § 155—159.)

558. *a.* The occurrence of *perforation of the intestines*, and consequent *peritonitis*, should not be overlooked in the enteric complication, or other severe forms of low nervous fever. Peritonitis seldom arises except from this cause, for large patches of the mucous surface, with PEYER'S glands, may be destroyed by ulceration; and yet the peritoneum will be unchanged. When, however, diarrhoea has been suddenly arrested early in the disease, by an injudicious use of astringents, general peritonitis and effusion may result without perforation, and even without ulceration. But this is only one of several bad consequences which may proceed from injudicious interference. If, in an advanced stage of fever, and after thirst, diarrhoea, tympanitis, and great prostration of strength, the patient suddenly complain of pain in some part of the abdomen, extending over it, with tenderness, increased distension, and rapid sinking of the powers of life, peritonitis has occurred. In this case large doses of opium, to palliate the patient's sufferings, are the only means that can be used with any benefit. — Dr. STOKES, who has very ably elucidated the subject of peritonitis from this cause, and its treatment, directs one grain of opium to be given every hour, or two hours, until a decided effect is produced by it; and afterwards at longer intervals. (*Dublin Hosp. Rep.* vol. v.; and *Dublin Jour. of Med.* vol. i. p. 125.) When effusion of the intestinal contents into the peritoneal cavity occurs, the result must be fatal. But when adhesion of the peritoneum to the opposite surface takes place previously to the perforation, or when the perforation is speedily followed by a limited inflammation and effusion of lymph, recovery is possible. The formation of coagulable lymph can hardly, however, be expected in peritonitis occurring in the course of fever; as the states of vital action, and of the circulating fluids, are generally incapable of producing it.

559. *b.* *Treatment of putro-adynamic fever* (§ 472). — The phenomena which especially characterize this variety, may appear either at an early stage of fever, or at an advanced period, — they may be the concomitants, or early consequences, of depressed vital energy, and imperfect powers of reaction; or the results of vascular reaction being so great, relatively to the state of vital influence, as to exhaust both the irritability of contractile parts, and the tone of the extreme vessels. In either case, alterations of the circulating fluids, and deficient vital cohesion of the soft solids, speedily follow, and coexist with these changes. In conformity with this view, with the pathological facts stated above (§ 523.), with a recognition of the characters of epidemics which have been observed in modern times in different countries, and with the results of personal observation, it may be safely inferred, that the treat-

ment of this fever should mainly depend upon the state of vital action early in the stage of excitement, and the period of the disease in which the putro-adynamic signs appear; and that, in a practical point of view, it will be, therefore, advantageous to divide this variety of typhoid fever into, — 1st. *The consecutive putro-adynamic*, or that form which is contingent on more or less manifest reaction; and, 2d. *The primary putro-adynamic*, or that which is attended by imperfect, or no, reaction, and in which the characteristic phenomena appear early in the disease. It should, however, be recollected, that both these forms may occur in the same epidemic, or that either may predominate; and, moreover, that the first or contingent state of putro-adynamia is sometimes met with in all epidemics, whether the fever be common synochoid, typhoid, or exanthematous, owing to the causes stated above, and with a frequency relative to the prevalence of these causes. (§ 502—504.)

560. *a.* *The stages of premonition and of invasion* of this variety, are scarcely different in their characters from those announcing nervous or typhus fever. The same means as have been advised above (§ 543.) may, therefore, be resorted to, with the intention of preventing the further progress of disease, or of rendering it more mild. — When the symptoms of invasion are either indistinct or protracted, the consequent fever is often rendered much less dangerous than it otherwise might have been, by the adoption of the measures already detailed, and more particularly by exhibiting an energetic *emetic*, and by promoting its full operation by warm or tepid mucilaginous diluents. Tepid *sea water*, or a weak solution of common salt in a tepid state, has been employed with advantage, for the purpose either of promoting the action of the emetic, or of producing full vomiting, when there has been nausea or sickness.

561. *β.* In the *consecutive putro-adynamic*, or when the *stage of excitement* is more or less developed, — when the pulse is frequent, full, or sharp; the skin hot, and thirst considerable, or if an internal heat be felt; vascular depletion may be practised, but with due reference to the circumstances of the patient, and to the period which has elapsed from the time of invasion. So long as the characters of putro-adynamia have not appeared, these symptoms fully warrant a cautious recourse to depletion; and in young robust persons, even a repetition of it. — If rigors and shiverings are followed by inordinate or tumultuous reaction, the necessity of larger depletions is obvious. But, even in this case, they should not be carried too far, or to the extent of producing syncope; otherwise, in attempting to avoid the exhaustion consequent upon excessive action, a quantity of blood may be withdrawn, too great for the diminished power of tonic contraction possessed by the blood-vessels, — the vessels being incapable, owing to the loss of their tone, to accommodate themselves to, or contract sufficiently upon, their contents, when the reduction of these contents is great, — and thus collapse of vascular action, and of vital power, may follow.

562. *γ.* In the *primary putro-adynamic*, or in cases attended by indistinct signs of invasion, and by imperfect reaction, we can hardly venture upon depletion, unless indications of congestion

or prominent affection of an important organ present themselves. In this instance, local depletions, or dry cupping, may be tried. If petechiæ appear early in these cases, or if the pulse be very compressible, very small, or broad and open; if the skin be cool, damp, or unnatural, yet not hot; if the tongue be flabby, or covered by a dirty mucus, although the fever is evidently not far advanced, or is very recently passed the stage of invasion; then bleeding should not be attempted. In this case, very different means must be employed; and with an energy proportionate to the prostration of strength attending these symptoms. If petechiæ, or vibices, or blotches, have appeared on the skin, they will furnish an additional indication, particularly if they assume a dun, or dark, or livid colour; and will indicate the propriety of having recourse to the tonics, stimulants, and antiseptics, and the combinations of them, about to be noticed.

563. *δ.* In *either form* of this fever—in the *first*, after depletions, in the *second*, after the operation of an *emetic*, which should be given at any time during the invasion, or for three or four days afterwards—the bowels ought to be freely evacuated, by either of the mild *purgatives* mentioned above, and by the occasional use of laxative enemata; and frequent but small doses of *nitre* may be afterwards exhibited in the saline medicine already prescribed, or of the *hydrochlorate of ammonia* in camphor mixture, or any other suitable vehicle. These latter are more especially indicated, if any heat is felt in the region of the stomach, and if the tongue is red at its edges and point. If there be increased heat of skin, tepid sponging the surface with the weak nitro-hydrochloric solution, or with a mixture of pyroligneous acetic acid, rose-water, and camphor mixture will prove both grateful and beneficial.—It is seldom, even in the primary putro-adyndamic, that *tonics* are productive of much benefit very early in the disease. But, when exhibited with *refrigerants*, they are often of great service. The infusion or the decoction of cinchona, either with the solution of the acetate of ammonia and nitrate of potash, or with the hydrochlorate of ammonia, a few drops of hydrochloric acid, and sometimes also with hydrochloric ether, is the kind of tonic which I can recommend from experience, as being the most suitable to an early stage of adynamic fever.

564. It is in this variety of typhoid fever, more especially, that the question as to the superior efficacy of alkaline medicines and of the non-purgative salines, or of mineral and vegetable acids, becomes a matter of extreme importance. Of the latter I can speak from observation; of the former I have not yet made sufficient trial to enable me to form a satisfactory opinion. It were to be desired that Dr. STEVENS, who has so strongly advocated the use of alkaline and saline substances in this fever, would furnish us with that sort of evidence of their efficacy, which would justify an early and decided recourse to them; and that those, who have ample means furnished them of settling the question at issue, would at last put it beyond the reach of cavil. That these substances are beneficial, at least several of them, is fully shown by the experience of successive ages and of numerous writers. This is the case in respect of nitre, hydrochlorate of ammonia, and chlorate of potash, of the excellent

effects of which I am convinced by repeated observation. But the superiority of alkaline carbonates over acids, has not yet been proved. It is also doubtful, whether or not the benefit found to result from the former has not chiefly proceeded from the medicines with which they have been combined. At present we are guided in some measure by what we know of the physiological action of these substances. The fixed alkaline bi-carbonates redden the blood when carried into it, but they relax the tone of the digestive mucous surface. Nitre produces a similar change in the blood, and resists any tendency to decomposition. Acids constrict the mucous and contractile tissues, impart firmness to the coagulum, but render the blood more dark than natural. With these imperfect data, the experience derived from accurate observation ought to be our chief guide; and whether we adopt acids in the earlier stages of the disease, and alkalies subsequently, or reverse this order, or even prescribe, in conjunction with neutral salts, either an acid or an alkali in excess, much difficulty will be felt in ascertaining how much is due to either of these means, and what may be legitimately imputed to other remedies, with which we may be morally bound to combine them, in order to render their beneficial operation more certain. When certain remedies, which have been particularly recommended in this form of fever, come under review, these substances will receive further attention.

565. In various states of putro-adyndamic fever, *external derivatives* will be required, as in the other varieties. When bloodletting is necessary at the commencement, they should follow this operation, particularly when prominent affection of an important organ exists. As to the choice of derivatives, little need be added to what has been already advanced. If blisters be adopted, attention is sometimes required to prevent spreading or sphacelating sores. They should, therefore, be applied only until they cause redness of the surface; when they may be followed by a warm poultice. Equal care is necessary to prevent sphacelation of the parts pressed upon in bed, and the occurrence of foul sores, from the contact of the morbid excretions, or from both causes conjoined. The means likely to counteract or remedy this occurrence have been stated above (§ 166.).

566. *ε.* In the *modifications* of this fever, noticed above (§ 476.), a decided recourse to the same medicines as are necessary in the advanced stages of the regular form, must be had, more particularly when signs of colliquation are early and prominent. The intention in this case is to arrest the progress of the changes of the blood, by supporting the powers of life, and promoting the functions of excretion. If it should be found possible to correct, in a more direct manner, the state of the circulating fluids, this indication ought also to be adopted, and the means which operate in this way resorted to. In conformity with the former indication, full vomiting should be induced, if it have not already taken place, and a mild stomachic purgative afterwards given. This latter ought to be repeated, according to the state of the bowels, and the appearance of the evacuations, which will furnish indications for the employment also of enemata, and indicate such as are most appropriate. In the worst forms of erysipelas, and in diffusive inflam-

mation of cellular structures, I have found equal parts of the decoction of cinchona, and the compound infusion of senna, with tartrate of potash, carbonate of soda, and compound tincture of cardamoms, an excellent purgative, and I see no reason against its use in this state of adynamic fever. After the bowels have been freely evacuated, decoction of cinchona, or a strong infusion of valerian, with chlorate of potash, and chloric ether, may be prescribed, according to the severity of the disease. Of the good effects of the decoction of cinchona with the compound tincture, nitrate of potash, and carbonate of soda, I can also speak from experience. When the prostration of strength is extreme, a pill containing two or three grains of camphor should be taken with each dose of either of these, at short intervals.

567. Other tonics, and different combinations of them from these now mentioned, will frequently be productive of great benefit, when morbid excretions have been evacuated. However specious the arguments adduced by some writers against the employment of *acids* in the putro-adynamic states of fever, it cannot be denied that good effects have been produced by them, especially when exhibited with powerful tonics. The infusion or decoction of cinchona, with hydrochloric acid, or with nitro-hydrochloric acids, and chloric ether (formerly CLUTTON'S febrifuge); the sulphate of quinine with sulphuric acid, and HOFFMANN'S anodyne; and pyroligneous acid in large doses, with camphor, the solution of the acetate of ammonia, and tonic or aromatic infusions, or the infusion of serpentaria or of arnica, are the most energetic, and may severally be tried, according to the peculiarities of the case. A solution of camphor in acetic acid was a favourite medicine with many writers on putro-adynamic fever, and was employed by them both internally and externally.

568. Dr. STEVENS'S saline treatment is most appropriate in this form of fever. He directs twenty grains of the chloride of sodium, thirty grains of the carbonate of soda, and eight of the chlorate of potash, to be given every two or three hours—or more or less frequently according to the urgency of the case—dissolved in water, in the advanced stages. He believes, that when these salts are prescribed before the stomach has ceased to perform its functions, they will not irritate the alimentary canal, but will be absorbed into the circulation and correct its morbid state. One or two table-spoonfuls of common salt may also be administered occasionally in a tepid gruel enema. The strength should, at the same time, be supported by strong beef tea, or the regimen about to be recommended.

569. ζ. If putro-adynamic fever be attended by predominant affection of any organ, local depletions, followed by external derivatives, will be necessary, particularly in an early stage of the fever.—At a later period external derivation, and the other means advised for the complications of nervous fever, according to their seat, should be employed. In this variety, however, a more liberal use of tonics, conjoined with the antiseptics just mentioned, is generally required.—When this or any other form of typhoid fever is complicated with asthenic inflammation of the fauces or pharynx, or both, the means already recommended are quite appropriate. In these cases, deglutition is very difficult, and sometimes impossible. Re-

course to external derivatives, and to injections, is then urgently required. The action of the bowels should also be solicited by purgative enemas, unless diarrhoea exist; and the medicines that are indicated should be administered in clysters, and in sufficiently large doses. As the patient is generally unable to gargle his throat, advantage will sometimes accrue from syringing it with any of the tonic mixtures above prescribed, or with a solution of the chloruret of lime or of kréosote; and if a part, or the whole, or either of these, should be swallowed, the more benefit will be derived.

570. η. If this variety become complicated with diarrhoea, disorganisation of the digestive mucous follicles and surface will rapidly take place, if the treatment be not prompt and judicious. The means already advised (§ 549, 550.) for this complication must be adopted in this case. If the diarrhoea occurs at an early period, it will generally be moderated by tonic infusions, with the nitrate of potash, or with the hydrochlorate of ammonia, and the compound tincture of camphor. A combination of ipecacuanha, nitre, camphor, and opium, or extract of poppy, will also often diminish or remove it. If hæmorrhage supervene from the bowels, these medicines will sometimes be sufficient to remove it. In more urgent cases the energetic remedies, previously directed (§ 550.), or the pyroligneous acetic acid, with camphor and créasote, or turpentine, &c., should be prescribed by the mouth, and in enemas. When diarrhoea or hæmorrhage characterises putro-adynamic fever, the alkaline carbonates will frequently aggravate or perpetuate it, and render convalescence protracted. In other respects, the treatment directed for the complications of nervous fever, and for its last stages, is also suitable to this; these stages requiring either the measures just described, or several of those about to be noticed, with a more or less direct reference to the putro-adynamic state, or various combinations of the substances already enumerated (§ 548—555.).

571. c. Treatment of exanthematous Typhus (§ 485.).—The premonitory and invading periods of this fever should be treated as recommended above (§ 543.), with the view of arresting or rendering more mild the procession of morbid phenomena.—a. In the stage of reaction the indications are—(a) to moderate excessive excitement; (b) to guard important organs from the effects of prominent action.—If full vomiting has not occurred previously, it should be excited by an emetic at the commencement of this stage, or on the first, second, or third, day of it. If, however, inflammatory signs have become evident, particularly if the lungs are affected, a moderate bloodletting should precede the emetic. The eruption, which generally appears in this period, is usually followed by slight alleviation of the symptoms, and should therefore be promoted by mild, tepid diluents, which may be made either diaphoretic, mucilaginous, or acidulous, according to circumstances. As to bloodletting in this disease it is pernicious in many, if not in most cases; and not merely in the nervous, but even in this stage. In the mild and regular typhus it is superfluous; but when a highly inflammatory character marks this period, or when local action becomes very prominent or excessive, it must not be omitted; otherwise the

local affection may run into disorganisation, and the nervous stage will be rendered more protracted or dangerous. The amount, repetition, and mode of depletion, will depend upon the peculiarities of the case.—When the bowels are open in this stage, *purgatives*, unless of the mildest kind, are unnecessary. Severe purging is prejudicial, as it derives from the skin, interrupts the regular course of the disease, and risks the production of the enteric complication. Tonics and stimulants are also injurious.

572. *β.* In the *nervous stage* the disease has induced a state of exhaustion, and the system requires to be supported, and even gently excited. HILDENBRAND recommends an *emetic* early in this period, if it have not been given previously; and *blisters* to be applied, about the seventh or eighth day, when the nervous stage commences. *Camphor*, with the solution of the *acetate of ammonia* and *nitre*, forms one of the best medicines that can now be exhibited. The quantity of camphor, however, should not at first exceed one grain every two hours, or a grain and a half every three hours.—*Arnica* was one of the medicines most commonly employed in Germany during the prevalence of this fever in that country, early in the present century. HILDENBRAND states, that its operation is stimulant, alterative, and, in large doses, emetic; and that it does not promote, but rather prevents, diarrhoea. In typhus it lessens the stupor, giddiness, and delirium, and increases the cutaneous perspiration; but it is useful only when the inflammatory character is quite gone. It should be given in the form of infusion, in a quantity short of producing nausea. This most able and experienced writer advises also, in the course of this stage, the use of volatile stimulants, especially the infusions of the roots of *angelica* and *imperatoria*, and of the flowers of the *calamus aromaticus*.

573. In the typhus epidemic, in the military hospitals in Vienna and surrounding countries, during the late war, where it was impossible to prescribe for the cases individually, the following plan was pursued by HILDENBRAND, with great success, in the simple and regular disease:—On the first day of the fever an emetic was administered, and succeeded by diluent diaphoretic decoctions. About the seventh day, when the typhomania and debility were increased, the skin and tongue dry, and the belly distended, blisters were put on the calves of the legs, and eight ounces of an infusion of two drachms of the flowers of arnica, and as much angelica root, with a little of HOFFMANN'S anodyne, were given daily, two table-spoonfuls being taken every two hours, alternately with camphor powders.—Stimulants, in this fever, should be prescribed in frequent but small doses, rather than in large quantities. Cinchona and other tonics are superfluous as long as the disease is mild and regular. But they, together with wine, &c., are required, if the putro-dynamic state appears in this stage.

574. *γ.* If the preceding stages have been prudently treated, and if the disease has been regular and mild, nothing more is necessary in the way of medicine, as the *period of crisis* approaches, than to promote the evacuations attending it; and, as the chief of these is perspiration, mild diluents, and the diaphoretics in common use, or those just mentioned, are to be continued. All medicines

should not be abandoned immediately after a crisis. Stimulants, however, should be milder, and given at longer intervals. HILDENBRAND advises the camphor and arnica to be given up, and the infusion of angelica to be continued for some time. As *convalescence* advances, the treatment should be chiefly dietetic and regimental.

575. *δ.* The *irregular forms of typhus*—the modifications and complications—require appropriate means, or variations, of the procedure now recommended.—If the *inflammatory character* is violent, a more active antiphlogistic treatment is necessary. But the existence of deficient power, and the knowledge that the nervous stage must follow, should influence the practitioner. For an inflammatory state of the brain, or the semi-apoplectic state, bleeding generally and locally must be adopted, to an amount which the circumstances of the case will suggest. When the lungs are affected this practice, aided by antimonials, blisters, and diaphoretics, is equally necessary. If the inflammatory state be not entirely removed, and if it is not safe to bleed more, or if this state be prolonged into the nervous stage, external derivatives and antimonials are to be chiefly confided in. The same practice is applicable to the association of *hepatic disease* in this stage. The affection of the intestinal mucous surface requires the same treatment as was recommended in synochoid and nervous fevers (§ 549. *et seq.*)—Sometimes the *gastric* or *biliary* character predominates, particularly in summer and autumn, owing to impurities in the *prima via*, and accumulations of bile in the hepatic ducts and gall-bladder. Emetics are necessary in these cases especially, unless there are indications which forbid them; and mild purgatives, in the inflammatory stage—in the nervous, aperient clysters—should be preferred.

576. *ε.* In the nervous stage various irregularities often occur. If this character is excessive, or has taken place suddenly, large and repeated doses of volatile stimulants are necessary. Camphor, ammonia, ether, musk, cinchona, serpentaria, wine, opium, and blisters are severally useful, when judiciously combined. Phosphorus has been recommended for this state, but HILDENBRAND found it useless. During this stage a passive, asthenic, or nervous kind of inflammatory action may occur, particularly in the mucous surface of the intestines and in the mucous follicles; but it sometimes also affects the brain and lungs. When it attacks the *intestines*, there is a painful feeling excited by pressing the abdomen; the pulse is small and irregular or unequal; the belly is tympanitic or tense; and the stools very frequent and morbid. For this state a moderate or small local depletion; blisters, sinapisms, or hot turpentine embrocations, followed by warm poultices, over the abdomen; camphor, with hydrargyrum eum cretâ, and DOVEN'S powder, in large quantities of mucilage; or camphor with ipecacuanha, nitre, and opium; mucilaginous enemata, with extract of poppies, &c.; and the other means already mentioned (§ 550.); should be chiefly relied upon. If this form of inflammation, or of inflammatory congestion, attack the *liver*, tenderness and fulness in the right hypochondrium, and jaundice, generally accompany it, and a very dangerous complication results. Local depletion is sometimes of use, but as frequently it is of little service. Mercurials, excepting, perhaps, the hydrargyrum eum cretâ, are

still less efficacious. Blisters over the hypochondrium and epigastrium; frictions with rubefacient liniments in this situation; rubefacient applications on the insides of the thighs; emollient and aperient enemata, if the bowels require to be assisted; camphor, with nitre, or sulphate of potash, and anodynes; diuretics conjoined with mild diaphoretics; and the nitro-hydrochloric acid given internally with the spirits of nitric ether, or used externally as a lotion or wash; may severally be productive of benefit.

577. ζ . The nervous inflammation of the brain is indicated by sopor and profound typhomania, and should be combated by blisters on the head, by camphor, by arnica, and the means directed for this affection in nervous fever (§ 551.). If tightness of the chest and dyspnoea occur in the nervous stage, congestion of the weakened vessels of the lungs may be inferred. In this state a small bleeding, to the amount of four or six ounces, may be directed in some cases, and followed in all by blisters on the chest, and antimonials conjoined with camphor.

578. η . If the *putro-adyamic character* supervenes and predominates as the nervous stage proceeds, the debility, equally with the morbid state of the blood, requires attention. The preparations of cinchona, either with mineral acid, or with alterative neutral salts, large doses of camphor, wine, opium, and the other means directed for the various phases and complications of this condition, will be required according to the peculiarities of individual cases. If *diarrhœa* or *dysentery* comes on in this state, opium in large doses, but at distant intervals; warm dilute wine, with spices and other aromatics; mucilaginous and farinaceous liquids, or gruel with common salt, taken in small quantities but often, and administered in enemata, with syrup or extract of poppies; and the other remedies noticed above (§ 556.); should be prescribed. — If *singultus* or *meteorismus* occur, they should be treated conformably with the principles already explained (§ 557.). — Swellings of the parotids are unpleasant accidents, even when critical. They should be checked at first by keeping the bowels moderately open, and cold applications to them. If this end be not accomplished, then suppuration should be promoted by stimulating poultices; and the abscess should be early opened, in order to prevent contamination of the surrounding cellular parts. If gangrenous sores appear in any part, the means directed above (§ 166.), more particularly the chlorides, *créasote*, powdered bark, turpentine, &c., either severally, or variously combined, or in the form of wash, epithem, or poultice, ought to be promptly and assiduously employed.

579. iii. *Of certain Medicines, &c. in Typhoid Fevers.* — *a. Antimonials*, especially JAMES'S powder and tartar emetic, are frequently of service in the early stages of fever; the latter for its emetic operation, and its febrifuge or contra-stimulant action during excitement; and the former for this last effect, in connection with its diaphoretic influence. The remarks already offered respecting these medicines (§ 162.) are applicable to the use of them in the fevers under consideration. It is chiefly in the early periods, in the more inflammatory states, in the pulmonary complications, and either in aid of, or as substitutes for, blood-letting, that they should be employed, more par-

ticularly the potassio-tartrate of antimony. However, the results of RAZORI'S practice, and the recent trials made of this medicine by Dr. GRAVES, in the advanced stage of typhus, indicate the propriety of having recourse to it, at a later period, in much more liberal doses than have been hitherto considered safe. This able physician, reasoning from the good effects of the medicine in delirium tremens, was induced to resort to it in a case presenting a quick, failing pulse; a black, dry, tremulous tongue; tympanitis; low, muttering delirium; startings of the tendons, and nervous agitation. He prescribed four grains of tartar emetic, in eight ounces of camphor julep, with a drachm of tincture of opium—a table-spoonful to be taken every second hour. The patient vomited after the second dose; and, after the fourth, he fell into a calm sleep, and soon recovered. Besides the good effect of this medicine, that of vomiting at this stage of fever, as recommended by many of the older writers, is shown by this case. Dr. GRAVES refers to other instances (*Lond. Med. and Surg. Journ.* vol. vii. p. 541.), in which tartar emetic and opium produced decided benefit, in most unfavourable states of the advanced periods of low nervous fever, and of exanthematic typhus. The combination of the potassio-tartrate of antimony with nitre is most appropriate in the stage of excitement; but, in the nervous stage, opium seems indispensable to the good effects of the antimony.

580. *b. Of other antiphlogistic and contra-stimulant means*, it is unnecessary to add any thing to what has been already advanced. The contradictory opinions entertained as to the propriety, or amount, of depletion are readily explained, when the various forms of typhoid fever, and circumstances of the case, are taken into consideration, in connection with the intentions with which bloodletting on the one hand, and *restoratives* on the other, are resorted to; and with the fact that both are very frequently required, not only consecutively but even simultaneously. This circumstance was well known to very many of the numerous writers on these fevers during the three last centuries, both in this and in foreign countries. They well knew and strenuously inculcated the fact, even as late as the days of CLARKE, that, in order to prevent the accession of the putro-adyamic state, it is necessary to bleed, and to use other antiphlogistic remedies, with decision, early in various fevers and epidemics. And next to bleeding, nitre and the hydrochlorate of ammonia were held in estimation, for their effects in lowering morbid reaction at the commencement of typhoid fevers, and in preventing putridity in advanced stages. Thus, whilst nitre was conjoined with antimonials, ipecacuanha, small doses of camphor, or with the spirits of nitric ether, to fulfil the former intention, and to promote perspiration and the action of the kidneys, it was given with tonics and stimulants, to produce the latter indication. The writings of DELIUS, HILLARY, HAENEL, WOOD, RAZORI, and many others, show us how very little we have hitherto improved upon their practice in these fevers. The same remark applies to the use of the hydrochlorate of ammonia, whose operation as a refrigerant antiseptic and tonic, ranks it as one of the best and most generally applicable of the many remedies employed in fever.

581. *c.* As to the use of *alvine evacuations*, we have arrived at similar conclusions to those very generally acted upon during the seventeenth and eighteenth centuries, but partially lost sight of towards the close of the latter. The good effects of *emetics* at the commencement of typhoid fevers were almost universally admitted, until BROUSSAIS banished them from his code of therapeutics.— That circumstances sometimes occur, which either render them unnecessary, or even forbid them altogether, has been allowed; but very sufficient evidence has been adduced of their good effects, more particularly in the periods of premonition and invasion, and even early in that of excitement. Many writers of great experience, especially CHEYNE, TUOMY, STOLL, SANDIFORD, REIL, HILDENBRAND, HUFELAND, &c., have advised them in the advanced stages of these fevers; and although they are rarely employed in these periods by practitioners in this country, I believe that they will often prove of service even then, when judiciously resorted to, in exanthematic typhus. The injurious effects imputed to them by MARCUS, WENDELSTADT, BROUSSAIS, and others, are to be referred to the employment of them in the gastric complication, and in other circumstances which contra-indicate their use.

582. The operation of *purgatives* in low fevers is now well understood; the indiscriminate use of them encouraged by the writings of HAMILTON having been checked and tempered by the partial adoption of the views of BROUSSAIS. And yet I believe that the particular state of the intestinal mucous surface that exists in these fevers may be increased by a neglect of this class of medicines; and that, when appropriately combined, many of them are calculated to prevent, or to alleviate, the morbid condition which the disciples of Broussais imagine them to produce.— A tolerably active purgative early in excitement, or in the other circumstances above noticed, both lowers excessive action, and removes morbid excretions, which, if allowed to remain, would prove a cause of irritation and contamination to the frame. In cases, however, where the vascular excitement is attended by vital prostration, either early or late in the disease, the use of purgatives requires much caution. When excitement is considerable, *calomel* with jalap, or with rhubarb, will be given at first with advantage; but, in other circumstances, the calomel should be withheld. When, with excitement, there is considerable pulmonary affection the potassio-tartrate of antimony may be added to the purgative adopted, as advised by Dr. M'CORMAC, and indeed very generally adopted in practice. But when vital depression is the predominant feature of the disease we should be as cautious in the use of purgatives, as in having recourse to bleeding. The evacuation of the serous portion of the blood by means of the former, is nearly equally depressing with the latter operation. In the advanced stages, and especially when putro-dynamic signs begin to appear, the blood-vessels, owing to the loss of a great portion of their tonic contractility, cannot accommodate themselves to the evacuation of much of their contents, in whatever way it may be effected; for the column of blood in the vessels is no longer presented to the contraction of the ventricles in that state of tension which favours its healthy circulation. If

the bowels, however, require the aid of a purgative, during a state of prostration, it ought not to be withheld; but it should be so selected, as to produce no greater evacuation than may appear requisite, and be so combined as to leave a tonic or salutary impression upon the digestive mucous surface. In such cases, equal parts of the compound infusions of gentian and senna, or an infusion of cinchona and rhubarb, or the compound decoction of aloes, or rhubarb and carbonate of soda, or the purgatives already mentioned (§ 150. 151.), or some of those prescribed in the *Appendix* (F. 180, 181. 205. 216. 252. 433.), may be resorted to. In the putro-dynamic form, and in the advanced states of typhoid fever, purgatives ought to be always combined with tonics and aromatics. They should never be given, excepting very manifestly required; and then in moderate doses, and combined as now advised, particularly when there is diarrhoea, or evacuations of blood, or meteorismus. However, rhubarb, or turpentine, in small or moderate doses, with aromatics, will often be of much service in such cases.

583. *d.* There are several *stimulants* of great use in low fevers; and which, owing to their peculiar or febrifuge operation, may be given with great benefit in that state of excitement which is attended by vital prostration, as well as in more advanced stages of the disease. Of these the most applicable and beneficial is *camphor*. This substance is most generally adopted; and has received the encomiums of most writers on typhoid fevers and more particularly of RIVERIUS, STOLL, FERRO, HOME, MARCUS, THOMANN, GEBEL, REIL, SCILEGEL, HORN, and HILDENBRAND. I have prescribed it not only in these, but also in pestilential, exanthematic, puerperal, and common continued fevers; and am satisfied as to its good effects; either when exhibited alone, or when combined with other appropriate medicines, and given in proper doses. In the *stage of excitement*, the dose, and the medicines which should be associated with it, should have reference to the state of vital power, to the mildness or severity of the disease, and to the nature of the prominent affection or complication. In this stage, particularly if vital power is not much lowered, it may be given in frequent doses of half a grain, or a grain, with a weak solution of the acetate of ammonia, or in a mixture with it and spirits of nitric ether, or with nitre (F. 494. 496.), or with hydro-chlorate of ammonia (F. 431.), or with antimonials (F. 493.), or with any two or more of these. It may be also exhibited in some circumstances, with advantage conjoined with calomel. If vital power is much depressed in this stage the dose of the camphor may be increased, and the antimonial or the calomel omitted, or given merely at the outset. In some one or other of these combinations, it will prove of benefit, whatever complications the fever may present. As the disease passes into the *nervous stage*, and more especially as this stage passes into extreme exhaustion, the dose of camphor should be increased, and it may then be conjoined with tonics, various stimulants, antiseptics &c., as arnica, cinchona, serpentaria, valerian, angelica, opium, sulphate of quinine, the chlorides, musk, aromatics, &c., according to the period and peculiarities of the disease. Many of the best writers in Germany prescribe it, early in the nervous stage, with

arnica, or with acetic or citric acid. HAUTERSIERK, CALLISEN, LUDWIG, BONNEVAULT, FRANK, JAEGERSCHEIDT, and HUFELAND direct a solution of camphor in acetic acid to be taken internally, and used externally, early in most states of typhoid fever. With the pyroligneous acetic acid, the camphor may be conjoined with still greater benefit. The inflammatory state of any organ, supervening in the course of typhoid fevers, does not contra-indicate the use of camphor, if given appropriately to the degree of vascular action and of vital power.

584. *Arnica* has been very much employed in Germany in low fevers, and in the nervous stage of typhus, yet it has not received a satisfactory trial in England nor in France. STOLL, FISCHER, COLLIN, FERRO, MERCIER, FRANK, RICHTER, HECKER, HILDENBRAND, and other high authorities recommend it, generally as directed above (§ 572.). QUENTIN prescribes an infusion of it with valerian. The flowers and the root are most commonly employed, and usually in the form of a weak infusion (F. 222, 223.).

585. In the low nervous form of typhoid fever, as well as in the nervous stage of exanthematic typhus, or in that stage and state of the disease for which the German physicians prescribe *arnica*, *valerian* may be employed with advantage. MATTHEI, FRIZE, REIL, THOMANN, and others recommend it. I have given an infusion of it in several cases, and made it the vehicle of other medicines, particularly the chlorate of potash, camphor, the alkaline carbonates, serpentaria (F. 269, 270.), &c. It is indicated in such states of fever as require a gentle tonic and stimulant of the nervous influence, especially when the nervous symptoms are prominent, although the head be cool and the pulse weak. In these circumstances it may be conjoined with camphor, tonics, &c.

586. *Serpentaria root* was praised by FRIZE, STOLL, REIL, MARCUS, and others, in the advanced stage of low fevers, and in the circumstances just mentioned. It is still used, when the skin is cool or the pulse is weak, and when warm stimulating tonics are required. It is most serviceable in the form of infusion, with aromatics and tonics (F. 262. 416. 826.). *Angelica root* was recommended by REIL; *imperatoria root*, by HOFFMANN; and the root of *calamus aromaticus* by HILDENBRAND. They are very rarely employed in this country, although they are of service, particularly in the form of infusion, as vehicles for other medicines, and on account of their warm, diaphoretic, and stimulant effects. They may be employed variously combined with each other, or with camphor, tonics, &c.; and are indicated in the same circumstances as require the use of *arnica*, viz. in the low nervous and putro-adyamic states. Their infusions are good vehicles for tonics, the chlorates, or alternative salts. I have sometimes prescribed them with chloric acid and chloric ether, or with the chloride of sodium and chlorate of potash.

587. *e. Cinchona and other tonics* have been praised by HUXHAM, LIND, LANGRISH, GRANT, WESTPHAL, SIMS, VALLISNERI, CASSON, FORDYCE, and most of the writers on fever during the last century, and by many contemporary authors; whilst others have attributed more or less mischief to their use. When the various forms of typhoid fevers, their complications, and the very different pathological states in the successive stages

of their course, are considered, this contrariety of opinion is easily explained. When the nervous stage has appeared, and when the putro-adyamic state is pronounced, whether early in the disease, as in the putrid or septic variety, or in the advanced stages of the nervous and exanthematic, the preparations of *cinchona* and the *sulphate of quinine*, are the best tonics that can be selected, both for the permanence of their action, and for their influence in arresting the disposition to colliquation that pervades the fluids and soft solids of the frame. In the early states of the disease, and where the propriety of having recourse to tonics is a matter of doubt, the *infusion of bark*, with the solution of the acetate of ammonia, and spirits of nitric ether, or the *decoction of cinchona* with nitre and hydro-chlorate of ammonia (F. 437, 438.), will generally prove serviceable.

588. *f.* The propriety of having recourse to *acids* in the states of low fever just alluded to has recently been disputed; and if the effects produced by them on the blood be considered, as shown by the experiments of FRIEND, ELLER, GIANELLA, HALLER, &c., and as stated in the article BLOOD (§ 135, 136.), rational doubts of their salutary influence may be entertained; yet the experience of most writers is in favour of them, particularly in fevers of a low character. SPANGENBERG, HUXHAM, LANGRISH, WOOD, MURSHINNA, ROWLEY, BOYER, RADEMACHER, SCHLEGEL, HORN, FORDYCE, BANG, MILLAR, FRANK, HUFELAND, &c. recommend the *mineral acids*, especially the hydrochloric in the circumstances mentioned above. From a careful observation of their effects in many cases, I believe that they will prove beneficial in some cases, and injurious in others, according to the period and state of fever, and the mode of prescribing them. If they are given before the blood has become materially altered, and the vital energy much exhausted, but after requisite vascular or alvine evacuations have been carried sufficiently far — whilst the skin is still warmer than natural, and whilst the pulse is broad, open, and compressible, the mineral acids, with tonic infusions, will generally be serviceable. In this state the infusion or decoction of *cinchona* may be given with hydrochloric acid and chloric ether; or the sulphate of quinine, with infusion of roses and sulphuric acid, or also with sulphuric ether. When the prostration is considerable, this latter may be the more energetic medicine. In more doubtful cases, particularly when the heat of surface is great, the infusion of *cinchona* or of *valerian* may be given with the nitrate of potash, or with the *nitrate of soda*, a few drops of nitric acid, and the spirits of nitric ether; and when the skin is cooler, either of these infusions, or some one of the others already mentioned, may be prescribed with equal parts of the *nitro-hydrochloric acid* and the tincture of *serpentaria*.

589. In the treatment of typhoid fevers it should never be forgotten that the state of the circulating fluids depends chiefly, if not entirely, upon that of the organic nervous influence, and that agents which apparently deteriorate the blood may yet be of use by administering to this influence. The *carbonic acid gas* was supposed by JANSENN, FORTIER, and PERCIVAL, to act as an energetic tonic, when taken into the digestive canal; and they therefore directed the use of those fluids which contain it most abundantly; and even

advised it to be thrown up the rectum. A similar practice was lately recommended by Dr. CLANNY, with the view of supplying the blood with this substance. But M. CHOMEL has shown the inefficacy of this practice (§ 538.). The acids which have appeared to me most serviceable in the early period of the adynamic, nervous, or putro-adynamic forms are the hydro-chloric and the pyroligneous acetic, particularly when given in the decoction of bark (F. 388.), or in either of the warm stimulant infusions mentioned above. When the nervous or putro-adynamic states are far advanced; when the temperature is low, and the skin lurid or discoloured; I believe, that whatever benefit follows the use of mineral acids, depends chiefly upon the salutary efforts of nature, or the substances prescribed at the same time. In the state just mentioned, the more energetic tonics and stimulants, in conjunction with camphor, the chlorate of potash, opium, wine, &c., are much more deserving of confidence. Besides cinchona and sulphate of quinine, other tonics, as cascarrilla, calumba, gentian, &c., may be used; but they are inferior to bark; and ought to be given chiefly in conjunction with substances appropriate to the peculiarities of the case. The willow bark has been recommended by OTTO, SCHLEGEL, WHITE, and HUFELAND, but it does not appear to be equal to cinchona.

590. *g.* The chlorates, &c.—The chloride of potassium (muriate of potash) was first employed, under the name of digestive salt, by SYLVIVS; and, owing to its febrifuge properties, it afterwards obtained the appellation of febrifuge salt of SYLVIVS. It was given in doses of from one to two or three drachms: and, although its action is stimulant, aperient, diuretic, and antiseptic, it has seldom been used in modern times. It is of service in the low stages of fever, and when there is evident change in the circulating and secreted fluids; but it is inferior to the chlorate of potassa in these states. This latter salt was recommended by GARNETT and some other writers, but at no time has it been generally used. I have prescribed the chlorate of potash in several diseases, since 1819, and consider it a valuable medicine, especially in the advanced stages of typhoid fevers. When excitement or vascular reaction is about to pass into the nervous stage, and when inflammatory determination has been removed, either of these salts, but the latter especially, will be prescribed with benefit. The chlorate may be advantageously conjoined with tonics and camphor; or it may be given in doses of five or seven grains every two or three hours, in tonic infusions, or in larger quantities at longer intervals.—A solution of chlorine, or of chloric ether, or of both, may be used in the same states, for which the chlorate of potash or the chlorides are here recommended.

591. The chloride of sodium, or common salt, although sometimes used, in various forms, but commonly as an aperient and anthelmintic, by the older writers, has recently been seldom resorted to, excepting in enemata, in the treatment of low fevers. Formerly putridity was much insisted upon as a characteristic of certain states of fever; for, owing to the intensity and concurrence of the exciting causes, to the treatment, and to the influences in operation through the course of the disease, these changes of the fluids

and soft solids, which, although not strictly putrid, yet somewhat resemble it, or even approach it, were common occurrences in the course of the inflammatory as well as of the adynamic varieties. These changes, inasmuch as they consist, in some measure, of an incipient dissolution of the vital cohesion of the tissues, and of the healthy condition of the fluids, quickly passing, with the disappearance of life, into manifest decomposition, were not altogether inappropriately termed putrid; and, for want of a more suitable name, they may still retain the denomination. With the modern disuse of this term, and from a disbelief of the possibility of putridity taking place in a living body, the operation of medicines in preventing or counteracting it was denied. Thus an antiseptic property was denied to medicines, although it could not be doubted that many substances had the power both of averting and of remedying the changes usually termed putrid. This power was imputed to their influence upon the nervous system, particularly the cerebro-spinal part of it. I have, however, shown at other places, by experiments performed by myself and others, that numerous substances are quickly conveyed into the circulation, where they directly change the state of the circulating fluids and secretions, and affect the organic or ganglionic nervous influence.

592. Conformably with this view, the older opinion as to the operation of antiseptics on the living, as well as on the dead body,—that certain substances prevent or counteract the changes usually denominated putrid or septic,—seems well founded. There can be no doubt that the circulating fluids are contaminated or altered in the course of fever, owing to the superabundance of certain constituents, and the loss of others necessary to the continuance of health. The impeded functions of the lungs, the skin, liver, and kidneys, in the early stage of the disease, will occasion the former of these changes, and the stop put to the functions of digestion and assimilation—to the sources of supply—will produce the latter. That the chloride of sodium is necessary to the healthy state of the blood, cannot be doubted; it therefore follows that the privation of it, for a number of days, during the treatment of fevers, will materially favour the morbid condition which the fluids assume in the advanced stages. But as other substances, as the chlorate of potash, hydrochlorate of ammonia, nitrate of potash, and nitrate of soda, act on the blood and on the economy in a similar manner to the chloride of sodium, although not so beneficially, universally, and permanently as this last, which has been so bountifully supplied by nature, we are enabled to account for the benefit derived from the use of them, in the advanced stages of fever, by writers in the sixteenth and seventeenth centuries. It seems very probable, that the common salt taken so abundantly with our food, after having produced the effects arising from its neutral state, is decomposed by the nervous or vital influence, or by the electricities circulating through the frame; and that each of its constituents performs ulterior offices in the economy, that are necessary to the continuance of health, and enters into new combinations, produced by the actions of the respective organs, in the circulating and secreted fluids.

593. If this view be just, the insufficient supply, or the privation, of this salt in the early stages,

whilst the discharge of it continues by the excretions, in either its neutral or its decomposed states, will cause a deficiency of it in the blood in the advanced periods of fever, and will give rise to further changes both in the circulating and in the secreted fluids. In conformity with this opinion, a modification of the medical and regimenal treatment, usually recommended in typhoid fevers, should be adopted. It is not improbable, that the evils resulting from a total privation of a substance so necessary to the healthy discharge of the functions, as the chloride of sodium is, would have been more generally manifest in these diseases, if other substances, acting somewhat similarly upon the blood and on the system, had not been commonly employed in the treatment of them. I have been led, by the antiseptic properties of certain medicines, to have recourse, in the latter stages of low fevers, to the most energetic of them, particularly the nitrate of potash, the chlorate of potash, the hydrochlorate of ammonia, camphor, and the terebinthates, cinchona, &c. in various combinations, either with each other, or with different stimulants and tonics. with the view of exciting the nervous influence, of supporting the powers of life, and of counteracting the changes, frequently terminating in a dissolution of the vital crasis and cohesion of the fluids and soft solids. But in fevers, which are characterised by excessive action at the commencement of excitement, and by extreme exhaustion, loss of irritability, and depravation of the fluids, in the latter stages, a too early recourse to some of these medicines may increase the morbid action, and aggravate local determinations; while a too cautious reserve of them, either as to quantity or as to the period of fever, may allow the diseased changes to proceed without interruption to a fatal issue. It is, therefore, imperatively required of us, that we should determine, by attentive observation, both the exact period in which medicines of this description should be commenced with, and the particular substances that should be first employed. As respects the kinds of fever just alluded to, as well as those forms which are either nervous, or more uniformly putro-adyamic, at earlier stages, we are at no loss for means, which are both refrigerant and antiseptic, and which may be employed from the commencement, either when excitement is most excessive, or when it is entirely absent, if due care be taken in the mode of prescribing them. By this early attention, particularly in putro-adyamic and inflammatory putrid fevers, to those means which may best preserve the fluids from the changes they are apt to undergo, especially when these fevers are left to themselves or injudiciously treated, the advanced stages are rendered much more mild and even manageable. The more refrigerant of the substances, formerly termed antiseptics, as nitrate of potash, nitrate of soda, hydrochlorate of ammonia, &c., when duly administered in the early course of fever, and combined with or followed by those which are more stimulant and tonic, as camphor, cinchona, chlorate of potash, arnica, &c., as exhaustion and signs of putro-adyamic appear, will generally prevent the more dangerous changes in the fluids from taking place. The *hydrochlorate of ammonia* is now seldom used internally, although HOFFMANN, JACOB, BARCHUSEN, LOESECKE, TISSOT, WERLHOF, MONRO, HIRSCHL,

HILLARY, M'CAUSLAND, GMELIN, and others, have recommended it highly in putro-adyamic fevers. I have frequently employed it; and Dr. CONWELL has found it of great service in the fevers of India. SCHMIDT prefers it in such cases as are attended by diarrhoea.

594. About the time when M. LABARRAQUE discovered the *chlorinated soda* and *lime*, cases of fever of a putro-adyamic or malignant form were frequently occurring in an institution to which I am consulting physician. I had made trial of various methods of treatment, but found camphor, in large doses, variously combined, and aided by other means according to the peculiarities of the case, the most successful of any. Shortly afterwards, M. LABARRAQUE'S process for preparing these chlorides was published at Paris; and as early as 1825 I procured them from Mr. MORSON, for the use of this, and another institution, to which I was physician. I employed them internally, in enemata, and externally, and as disinfectants; and the results were such as have induced me to have recourse to them ever since, in the various circumstances and diseases in which I have recommended them in this work. The *chlorinated soda* is a valuable medicine in all the typhoid forms of fever, when judiciously prescribed. It may be given early in the putro-adyamic variety, when excitement is imperfect or low, and the skin discoloured, or petechiæ are appearing, and continued throughout the disease. But when vascular reaction is considerable, or local determination prominent, particularly in the nervous and exanthematic varieties, this substance should be withheld, until these states are subdued, or about to lapse into the nervous stage.—At first it ought to be prescribed in small doses, so as not to offend the stomach—in from ten to fifteen drops of the solution, as prepared by LABARRAQUE, every three or four hours in camphor julep or in an aromatic water. As the disease passes into a state of exhaustion or of manifest putro-adyamic, or when there are a lurid skin, low muttering delirium, stupor, meteorismus, black sordes on the tongue, teeth, &c., the supine posture, unconscious offensive evacuations, petechiæ, blotches, a disposition to gangrene in parts pressed upon, coma, &c., it should be given in larger doses, or more frequently, and in tonic infusions or decoctions, or with camphor, serpentaria, or other stimulants and tonics. I have seen it productive of great benefit in such cases; but it should be commenced before these symptoms appear, and be persisted in, as its good effects are seldom manifest in less than three or four days, or more; and it should not supplant the use of wine, opium, suitable nourishment, and other means which the stage of the disease and peculiarities of the case may suggest. It should also be frequently administered in enemata; and the surface of the body ought to be often sponged with a stronger solution of it in warm water, with the addition of camphor. M. CHOMEL has lately given the chlorinated soda an extensive trial; and he states that it has proved more successful in low fevers than any other means, when perseveringly employed. Dr. GRAVIS has also recently employed it, and has found it extremely serviceable. It acts, first, on the tissues with which it is brought in contact, as a gentle stimulant and antiseptic; and is most pro-

bably partially decomposed in the digestive organs, and reduced to the state of common salt. In this state it is carried into the circulation, where it supplies the waste of this substance that has taken place in the early stage of the disease.

595. The *chlorinated lime*, in doses of one or two grains, may be also employed with great advantage. When exhibited in solution, it will be preferable to commence with half a grain every hour, or with a grain every two hours, gradually increasing the quantity as the stomach may tolerate it. It is best adapted to the more extreme cases of putro-*adynamia*, and especially to those attended by urgent diarrhoea and meteorism. In these it may be conjoined with camphor and other stimulants. It was employed by Dr. REID, of Dublin, in low fevers and in dysentery, a few months after the period of my having first had recourse to the chlorinated soda. It may be prescribed in the same circumstances and combinations as the latter; but is not so generally appropriate, nor does it admit of so early, or of so prolonged, an exhibition.*

596. *h. Alkalies and alkaline carbonates* have been employed in various states of typhoid fever, and frequently with service. The *sesqui-carbonate* and other *preparations of ammonia* have been very generally resorted to when diffusible stimuli have been required. In the early stages of these fevers, the *sesqui-carbonate* may be used, with advantage, to make a neutral saline mixture with the *pyroligneous acid*, and either the alkali or the acid may be given in excess, or the mixture may be taken whilst effervescing. The *preparations of ammonia* are most useful in the nervous and exanthematic varieties of typhoid fever; and in conjunction with camphor, or with tonic infusions, in the nervous stage. In the putro-*adynamic* state, they have seldom appeared to me to have any good effect, unless combined with these or other tonics.

597. The *sesqui-carbonate of soda* and *bicarbonate of potash* are seldom used unless to form neutral *citrates* or *tartrates*, and to obtain the fixed air given out during the combination. The advantages of this latter are, however, by no means considerable; but the salts themselves are of service, by supplying, in some respects, the place of that commonly employed. The *carbonate of soda* has been occasionally used, and is recommended by Dr. STEVENS as an ingredient in his saline powders. In the more *adynamic* states of typhoid fevers, or in the intestinal complications, the *carbonate of soda* should be given in a tonic infusion

or decoction, with camphor, and with opium, or extract of poppy, or compound tincture of camphor, to prevent it from relaxing the digestive mucous surface, and from increasing the diarrhoea. Unless it be thus combined, or conjoined with the chloric salts, which Dr. STEVENS directs, it may not only aggravate the affection of the bowels, but also favour relapses, or cause the disease to pass into the dysenteric complication. An *acetate of soda*, formed by *pyroligneous acid*, with an excess either of the acid, or of the alkali, according to the state of disease, and taken whilst effervescing, or afterwards, appears to me, from the few cases in which I have had an opportunity of using it, to deserve a more extensive trial.

598. The salts employed by Dr. STEVENS, viz. the chloride of sodium, the carbonate of soda, and the chlorate of potash, cannot be supposed to act, even upon the digestive organs, in the states in which they are prescribed, without undergoing some change from their mutual action, and from the fluids with which they mix. Indeed, the results may be assumed to be chlorates of soda and of potash, and carbonate of soda, taking the proportions of the individual salts into consideration. When these salts are taken into the stomach during the middle and latter stages of typhoid fevers, the passage of at least a portion of them into the circulation may be expected, and the loss of the saline ingredients of the blood in the early stages, argued for above (§ 592.), will be supplied. Upon this principle, and for the reasons there stated, this method deserves a more extensive trial than it has hitherto obtained; and when the nature of the salts, and the modes of their operation, are considered, it does not seem to differ materially from that by means of the chloride of soda, first adopted by myself. — There are certain points upon which Dr. STEVENS very strongly insists, and which are partly contradicted and partly confirmed by former observers: these are—1st, The superabundance of acid in the excretions; 2d, The influence of all acids in rendering the blood dark and grumous; and, 3d, The mischief produced by them in the latter stages of fevers. Now, without disputing the accuracy of the first statement, although a confirmation of it is required, I will admit the truth of the second; for it agrees with my own experiments, and with those performed by writers early in the last century, to whom I have referred in the article BLOOD (§ 135.). That acids will be injurious in the latter stages of fever, seems a rational inference from these experiments, in connection with the dark and morbid state of the blood at that time; and yet numerous writers have recommended them, and adduced proofs of their good effects even in the most malignant states of remittent, continued, and exanthematic fevers. The muriatic or hydrochloric, citric, and pyroligneous acids have been severally employed in these states, and found of service; but they have also frequently failed. That the blood is black and dissolved in scurvy cannot be doubted, yet the advantages derived from citric acid have been great, unless some remarkable delusions as to the causes and treatment of this disease have existed*; and

* Dr. REID mentions an important fact illustrating the cause of putro-*adynamic* fevers, — a cause which exists to a greater extent than is supposed, especially in large cities although in a much less degree than in the instance about to be adduced. At Valladolid, during the war in Spain, the palace of the “Holy Inquisition” was appointed for the barracks of a British regiment. Under the colonnade was a well, from which water could be drawn into the uppermost stories. This water had a sweetish decayed taste; but, for the want of better, the soldiers used it both for drinking and cooking. No other regiment in the garrison was so unhealthy; and the prevailing disease was putrid fever, of which there was not the slightest symptom in any of the other regiments. At last the reason was discovered: skeletons were found in the well, and several were observed with pieces of the flesh adhering to the bones. If the chlorides of soda or of lime had been then known, or if that which had been long previously recommended been employed, the mortality from this fever, and from putro-*adynamic* dysentery, would not have been so great as it proved during the Peninsular campaign.

* From several opportunities of observation, I am of opinion that scurvy has been often confounded with putro-*adynamic* fever; that both diseases formerly proceeded from the same causes, and often occurred simul-

such actually appears in some measure to have been the case. The truth, however, seems to be, that whilst pathologists have lately been occupied exclusively with the living solids, Dr. STEVENS has concerned himself only with the blood, and kept too much out of view the influence of life, especially as manifested in the organic nervous system, upon both the circulating and secreted fluids.

599. As far as my own observations enable me to form an opinion as to the respective merits of these acids, and of the alkaline carbonates and salts, I conclude—1st, That the *acids* may be of service early in fever, whilst vascular excitement is considerable, although vital power may be weak; that they seldom will be injurious in this period, as long as the skin continues warmer than natural, and the blood preserves its colour; and that but little confidence should be placed in them when the surface is at, or below, the natural temperature, or materially discoloured, unless they be conjoined with substances calculated to excite the powers of life. 2d, That the *carbonates of soda and potash*, the solution of *chlorine*, and the *chlorides*, are preferable in the middle and latter stages, more especially when the blood appears morbid, the skin discoloured, and the excretions offensive; but that the *sub-carbonates* should not be trusted to in the last stages of typhoid fevers, unless conjoined with substances calculated to support the vital energies; and that, at this period, *chlorine*, the *chlorates*, and *chlorides*, should be preferred, as being more tonic, stimulant, and antiseptic than the carbonates. 3d, That the *sulphate of soda*, the *phosphate of soda*, and the *sulphate of magnesia*, are severally of service in the stage of excitement, when they may be given, at first so as to act gently on the bowels, and afterwards in small doses, as refrigerants or alteratives; and that the *chlorate of potash*, the *citrates*, and *acetates* may likewise be employed with the latter intentions. And, 4th, That circumstances may occur, in which it will be advantageous to exhibit

taneously in the same camp, army, fleet, or ship; that the causes were chiefly putrid water, mouldy and adulterated bread, diseased and unwholesome flesh, vegetable and animal exhalations, insufficient nourishment, and the depressing passions; and that the protracted use of salted provisions of a good quality was but little concerned in producing either of these diseases. During the seventeenth and eighteenth centuries, trading vessels were provisioned as cheaply and as sparingly as possible, and fleets and armies were provided by contractors who enriched themselves and those who passed their supplies at the expense of the lives of thousands. Bread which was actually nauseous; the flesh of animals dead of epizooties; provisions which had been either salted for years, or nearly half putrid; numbers sleeping in a small space and in imperfectly renewed air; the constant evaporation from the too frequently washed decks; water kept in wooden casks until it became blackish, inky, stinking, and nauseously putrid; were causes of fever often in protracted and simultaneous operation. I have never been in a ship in any other capacity than as a passenger; but some of my voyages have been long, and have afforded me occasions of witnessing, even at the commencement of the nineteenth century, the existence of some of these causes. For many years matters have been altered, especially in the navy. The mutiny at the *Nore*; the advance of knowledge; the stricter attention to the supply, preparation, and quality of the provisions; the preservation of water in iron tanks, and some other subordinate circumstances; have done more to banish putrid fevers, dysentery, and scurvy from our fleets, than the use of citric acid or any other antiscorbatic or antiseptic; and I have no doubt that the prevention of these causes, and the general adoption of the chlorides, will be found the most certain means of preventing and of curing these diseases.

the neutral salts with either an acid or an alkali, as the chloride of sodium, with a vegetable acid, as prescribed by MORGAN; or with soda, as advised by STEVENS; or to prescribe saline substances with an excess of either of their constituents, as the chlorates with an excess of acid or of alkali.

600. *i. Opium, &c.*—Much difference of opinion has existed as to the propriety of giving opium in typhoid fevers. But when we find SYDENHAM, POLIDORI, ROLFINCK, SCHLEGEL, VAN HOVEN, HOME, HORN, MARCUS, LATHAM, STOKES, GRAVES, &c. favourable to the practice, the grounds of dissent from it ought to be carefully examined. There are circumstances and states of fever which forbid its use, but there are others which as imperatively require it; and I believe that the objectors err grievously in not discriminating between them, and in not studying either the conditions which contra-indicate it, or the modes of exhibiting it in the cases that would be benefited by it. SYDENHAM considered that it prevented coma or stupor, when given after vascular and alvine evacuations had been judiciously employed. ODHIELIUS, GILCHRIST, HOME, and GRAVES combined it with antimonials; and the propriety of the practice cannot be doubted, in the circumstances in which they employed it. In the present day, the indications for the exhibition of opiates have been so ably stated by two accomplished physicians—Dr. LATHAM and Dr. W. STOKES—that whatever I may advance as to this subject must in great measure be an echo of their observations. When the disorder of the sensorium outruns the other symptoms; when by venesection or topical bleeding, or by alvine evacuations and refrigerants, the general and local symptoms are relieved, but the delirium still continues; when to this state are added, tremors, subsultus tendinum, and unrestrained evacuations; when there has been at first high vascular excitement, and large evacuations have been required to guard the brain or other organs from mischief, and wild delirium has followed; if the patient has previously been in a delicate or nervous state; if he has been addicted to an excessive use of spirituous or vinous liquors, particularly the former; if the habits of the patient and his occupations have been such as to inordinately excite and exhaust the sensorium; or if the anxieties, the toils, or the debaucheries of life have previously injured the health, and more especially the state of nervous energy;—in these several circumstances should opiates be resorted to, in the advanced progress of typhoid fevers, and of synochoid fever that has passed into the nervous or typhoid state. On most of these, Dr. LATHAM has insisted with great precision and force; and I entirely subscribe to the value of his remarks. Dr. STOKES remarks, that *three* circumstances call for the use of opium in fever: 1st, Where there is persistent watchfulness; 2d, Where an inflammatory condition of the brain has existed, and been subdued, but delirium or other nervous symptoms still remain; 3d, Where an excited state of the sensorium exists without heat of scalp, or remarkable throbbing of the arteries of the head; and to these I may add a fourth, Where there are much relaxation of the bowels, unrestrained evacuations, tremors, watchfulness, or delirium, or subsultus tendinum.

601. The *mode* of exhibiting opiates is sometimes of great importance. In many cases, one or two grains of solid opium may be given, either alone, or with camphor and nitrate of potash. The combination with camphor is to be preferred, when there is much adynamia, and no inflammatory determination to the brain. When the bowels are very remarkably disordered, ipecacuanha may be added to these. The *acetate of morphia* is often superior to pure opium, when given in doses of from a quarter to half a grain, with camphor, or with aromatic spirits, or warm spices, as Cayenne, &c.: particularly in cases of extreme prostration. The *hydro-chlorate of morphia* may be preferred, if the chlorates are also prescribed. Opiates are sometimes of service when exhibited in small mucilaginous enemata. HILDENBRAND, who is averse from the use of opium in the exanthematic typhus, unless under circumstances manifestly indicating it, very justly remarks that, when it is determined upon, it should be given in a full or large dose, once or twice repeated after a proper interval, rather than in small and often repeated doses.

602. Other *narcotics* may be prescribed in certain states of typhoid fever, but they are not so deserving of confidence as opiates. The extracts of *poppy* and *hyoscyamus* are occasionally useful, particularly when opium disagrees; but even in such cases, the acetate of morphia, prescribed as just directed, will be of service. BRERA praises *belladonna* in the states of fever indicating the propriety of having recourse to opium. This narcotic is sometimes useful in the delirium attendant on erysipelas of the scalp. Mr. BLACKETT (*Lond. Med. Repos.* vol. xix.) recommends it in similar circumstances. It seems deserving of trial in the states of nervous fever mentioned above, and in the nervous stage of exanthematic typhus.

603. *l. The use of wine and of some other stimulants* requires much discrimination. It has been supposed by some writers, that *wine* is contra-indicated where there are delirium; a dry, black, or red tongue; red or suffused eyes; or much heat of surface. This is partly true; but one, or even more, of these symptoms may be present, and yet wine will prove of great benefit. Indeed, wine may be exhibited in the same circumstances as require the use of opium. When the delirium is of the kind above stated (§ 600.), and is accompanied with the same phenomena, &c.—when the state of the tongue is the result of extreme adynamia, inflammatory determination having been subdued—when the suffusion or redness of the eyes is the result of want of sleep, and is attended by a cool scalp—and when the heat of skin exists chiefly on the trunk, and is attended by indications of putro-adynamia—then wine will be given with benefit, and it is even indicated. This subject has been very ably canvassed by some contemporary writers, particularly by Drs. WILSON, PHILIP, ALISON, GRAVES, STOKES, and TWEEDIE, whose experience gives weight to their opinions; and they very nearly concur with me in the propriety of exhibiting wine with due precaution even in these circumstances, as well as in others which are less doubtful.—GILCHRIST, HURD, HALLS, WENSEL, HARLES, MATTHEI, HUFFLAND, HORN, and others, even notice the influence of wine in reducing the heat of skin,

in fevers tending to putro-adynamia, and my own experience confirms the observation.

604. The *indications* for the exhibition of wine in the typhoid states of fever may be reduced to the following:—(a) When the patient has been proceeding favourably, and the pulse suddenly becomes weak, very soft, or irregular; the skin cool or damp; the countenance collapsed; and the strength prostrated;—(b) When the patient complains of a feeling of exhaustion, and expresses his wish for wine or support;—(c) When vital depression occurs unexpectedly or suddenly, or without any evident cause;—(d) When the depression is owing to injudicious depletions, or excessive evacuations, or to the depletions or other means required to subdue inflammatory determinations at an advanced stage, or to protracted or excessive diarrhoea, or to hæmorrhage from the bowels, or from any other part;—(e) When, with these symptoms, the abdomen becomes tympanitic, and the exhaustion increases;—(f) When the delirium is low, muttering, and constant, and attended by tremors, or subsultus tendinum; the surface, and particularly the scalp, being cool, the pulse soft, weak, or small, and the posture supine;—(g) When petechiæ or vibices of a dark hue, and other signs of putro-adynamia, appear; the scalp being cool, and the action of the carotids not materially excited;—(h) If early convalescence be slow, unattended by local affections of an inflammatory tendency, and owing chiefly to debility;—(i) If, with one or more of the foregoing indications, or with a soft pulse, moist tongue, or cool skin, in the latter stages, it be ascertained that the patient has been addicted to spirituous liquors, or to wine in excess;—(k) and if the character of the epidemic be of a low kind, and if the early excitement be attended by weak vital resistance, and soon pass into exhaustion—then the propriety of having recourse to wine or other active stimulants, with requisite precautions, cannot be disputed.

605. The *kind* of wine, its *quality*, and its *quantity*, are deserving of particular attention.—Old sherry, Madeira, and white hermitage, of the best quality, should be preferred. The red and acid wines are most apt to disagree; yet port and red hermitage are useful in some cases, particularly when diluted, and conjoined with aromatic spices, in the form of negus. NAVIER recommends champagne; but it is suitable only to the stupor or coma attendant upon an extreme state of adynamia.—The *quantity* of wine given in the twenty-four hours should depend upon several circumstances; but it may vary from four or five ounces to sixteen or twenty. Dr. BATEMAN thinks that it should not exceed a pint: very much larger quantities have, however, been given with benefit; but these are only the exceptions from the general rule. Regard ought to be had to the age and previous habits of the patient, as well as to the state of the disease. Young persons are readily excited, and should take only the smaller quantities. Older patients, and those especially who have been habituated to much wine, or to spirituous liquors, often require the full amount just named. The use of it ought always to be commenced in small quantities, and increased as the indications may guide the practitioner. In all cases, it should either be

diluted, or given in the patient's food; and the effects carefully watched.—Dr. TWEEDIE justly observes, that, if the patient relishes the wine, if he is tranquillised by it, and if there is a gradual and steady improvement in the symptoms, without any marked excitement after it has been taken, benefit will result from it. On the other hand, if the pulse or heat of the skin are much or quickly raised by it; if the face becomes flushed, and the patient restless or incoherent; wine is either improper, or the quantity has been too great. If after having been stimulated, he soon lapses into the previous state of exhaustion, or seems weaker from each successive dose, no advantage will be obtained from it. When wine has produced the desired effects, it should be gradually withdrawn.

606. Other *fermented liquors*, particularly when bottled, and even *brandy*, have been used, in the circumstances indicating the use of wine. I have employed bottled stout with benefit. It is an excellent vehicle for the carbonate of soda or of potash, or for small doses of the hydro-chlorates, or for both conjointly, and is most appropriate to the advanced stage of putro-adyamic fever. Spruce beer, ginger beer, and Seltzer water, may severally be employed, and in a similar manner. Brandy ought to be much diluted, and is best suited to those who have been habituated to spirituous liquors. In cases attended by a protracted or colliquative diarrhoea, and extreme prostration, the brandy should be burnt, and given in some thin sago or arrow root.

607. *Yeast* has been frequently recommended in typhoid fevers. Dr. STOKER considers, that it may be given in all the stages in which it can be retained by the stomach, even when the existence of inflammatory complications prevents the use of other stimulants; and that it is generally easily taken alone, or with any other medicine, or in any vehicle that may be deemed advisable. In the worst forms of typhus, when it is most needed, he states that it is rarely rejected, but, on the contrary, is much relished; and that it is moderately laxative, often superseding the use of purgatives. If it prove not sufficiently aperient, he gives a little tincture of jalap in it; and if the bowels are too much relaxed, a few drops of tincture of opium are added to each dose. It appears to Dr. STOKER to correct the morbid contents of the alimentary canal, and the consequent symptoms of putrescence; petechiæ and black tongue being more effectually removed by it than by any other means. He has, therefore, substituted it for bark and wine, when they could not be employed on account of inflammatory symptoms, and has conjoined it with them when there was no such counter-indication. He prescribes the yeast in doses of two table-spoonfuls every third hour, with an equal quantity of camphor mixture. If administered in enemata, three times the above dose may be employed. Dr. STOKER, whose experience of this treatment has been long and most extensive, observes, that instead of increasing the tendency to tympanitic distension, by promoting fermentation, as may be objected, it actually prevents the accession of this symptom; and that, in the most obstinate instances of typhoid tympany, he has found enemata of yeast and assafoetida the most efficacious remedies.

608. *Other stimulants* require little attention. *Musk* has been recommended by the FRANKS, GEBEL, GELIN, MARCUS, HORN, STOKER, and others in cases of true adynamia—of extreme prostration, with much affection of the sensorium. It may be prescribed in the same circumstances as admit of the use of wine. THOMANN, however, found it quite inefficacious. It should be given in large doses to be of any service—from ten to fifteen grains, with camphor or ammonia, or other medicines which the peculiarities of the case will suggest. *Phosphorus* and *phosphoric acid* have likewise been employed. They do not appear to possess any claims to particular notice; but may be injurious if too liberally or inappropriately administered. I have seen benefit derived from the infusion of *green tea*, when the stupor or coma has been great; and I believe that strong *coffee* has sometimes proved useful in similar states. It has been recommended by ZAMBELLI and GRINDEL. The warm *spices*, especially *capsicum*, are often of service, and may be given in considerable doses in the latter stages of typhoid fevers, but chiefly as adjuvants or corrigents of other remedies. The *spirits of turpentine* are frequently productive of benefit, when prescribed in small doses, with aromatics or spices; but a large dose may be attended by very serious consequences, when exhaustion is extreme. It is an excellent medicine in enemata, with castor oil, chloride of sodium, or other purgatives when the bowels require to be opened; and with assafoetida, or extract of rue, when there is much tympanitic distension. Substances of a similar kind, or the usual carminatives, have been directed in enemata by THOMANN and HUFELAND, in order to remove this symptom; but the injection just recommended is the most certain in its effects. The means noticed above (§ 158.) may also be resorted to. When there is hæmorrhage from the bowels, these are generally efficacious. If they fail, a solution of the acetate of lead, in pyroligneous acid with the addition of *kræosote*, may be thrown up in any vehicle which the peculiarities of the case may require.

609. Many practitioners are averse from giving stimulants or tonics in typhoid fevers, from a fear of thereby aggravating or inducing inflammatory determinations. But even where the nervous inflammations noticed above (§ 495.) may be presumed to exist, and particularly in an advanced period of these complications, a judicious use of stimulants is actually necessary. It is a well known fact, and well expressed by Dr. W. STOKER, that, at a certain period of inflammatory affections, stimulants become antiphlogistics: and this is more especially the case in respect of these affections, when they occur in the course of fevers. The nervous energy is then depressed, irritability is most remarkably impaired, the fluids changed, and the whole constitution incapable of manifesting the phenomena, or of developing the lesions, constituting true or sthenic inflammation and its consequences. A spurious or asthenic state of action only, quickly passing into disorganisation, can possibly take place in these circumstances; and it can be remedied solely by stimulating and antiseptic means. These facts are frequently placed before our senses, and demonstrated by the treatment found most beneficial, as well by that most injurious, in malignant sore throat.

610. *l.* Various external means have been suggested for typhoid fevers. Some of the most serviceable of them have already been noticed. The cold affusion over the general surface is very rarely admissible in this class of fevers; but applied to the head only, it is often of manifest service, when the determination to the encephalon in the early stage of excitement is great, or when the delirium is high or maniacal, or attended by increased heat of the scalp, and excited action of the carotids. In these cases it lowers morbid action remarkably, and procures sleep. *Tepid bathing and sponging* are favourably noticed by BROCKLESBURY, WOLFF, JACKSON, HALLÉ, BRANDIS, and others. *Tepid or warm sponging* with a solution of the chlorides, or of the nitrohydro-chloric acids, or of camphor in pyroligneous acid, are deserving of general adoption. *Tepid or warm aromatic baths*, or sponging the surface with infusions or decoctions of aromatic plants, have been employed by MARCUS, HORN, HARLES, and DUPIN. KERESIG advises warm aromatic embrocations to be placed over the abdomen, when there is diarrhoea or meteorismus.—The use of blisters has been sufficiently noticed. They may be applied over, or near, the affected organ, when the affection consists chiefly of congestion, or impaired action. In other circumstances, they may be used as derivatives. This remark is applicable to the use of *sinapisms*, and to the warm turpentine embrocation. CALLISEN recommended *boiling water* to be used as a blister and derivative; and the idea has been adopted by some recent writers. One of the most beneficial external means that can be employed, is a liniment, consisting of the compound camphor liniment, with soap and Cayenne. This may be rubbed gently but assiduously over the hypochondria, or insides of the thighs, twice or thrice daily. I have occasionally resorted to this treatment, for upwards of twenty years, and often with great benefit. Several of the *liniments* prescribed in the *Appendix* may be used; but the Cayenne should be added, particularly when sensibility and consciousness are impaired.—*Dry cupping* may also be tried as a derivative, during the early or middle stages of the disease. In the putro-adyamic state it is seldom admissible.

611. *iv.* As to the *Prophylactic Measures* that may be resorted to in typhoid fevers, it is unnecessary to add any thing to what is stated above (§ 117. *et seq.*), and in the article INFECTION. The means there recommended are quite applicable to these diseases.

612. *v.* The *Diet and Regimen* in typhoid fevers are particularly deserving of attention. Both ought to be suited to the stage and form of the disease.—*a.* In the early period of excitement, the air should be pure, dry, cool, and without any current. The apartment should be large and open, the bed without curtains, and the air renewed, without exposing the patient to any chill. Barley water, fresh whey, rice gruel, or common gruel, with a little salt, when the excitement is low, or when thirst is not much complained of, may be employed as the usual beverage. The temperature of the drink, and of other ingesta, should be tepid or somewhat above it. If bronchial or catarrhal symptoms are present, warm, mucilaginous, and mild diaphoretic drinks should be allowed. It is improper in this stage to at-

tempt to excite perspiration by warm coverings. If stupor is present in this stage, the external senses may be stimulated, and neither light nor noise need be excluded.

613. *b.* In the *nervous stage*, the air of the apartment should not be too cool; and the bed-clothes ought to be warmer. An uniform temperature, and the purification of the atmosphere, must be always attended to. A cold, moist air, and currents of air, during this stage, induce diarrhoea, bronchial or pulmonary congestions, or other dangerous complications; whilst a too warm, close, and impure air, particularly when breathed by a number of persons, favours the development of putro-adyamic changes. The greatest cleanliness is requisite. Neglect of this produces gangrenous sores and ulcers, particularly where pressure is made, or slight bruises have been inflicted. The tongue should be scraped, and the teeth and mouth washed with salt and water, or gargled with them or with the chlorides, if the patient can do so. The hair may be cut off in the early stage; but the removal of it in this may be injurious, if the adynamia is extreme, and the scalp cool at the time.

614. In the nervous stage, bland, very digestible, and fluid nourishment may be allowed. The drinks should be mucilaginous, and gently warm. Whatever food or drink is used, whether gruel, thin arrow-root, &c., or weak animal soups, broths, beef tea, &c., should contain the usual quantity of salt, for the reasons stated above (§ 593.). If the treatment by the chlorides, &c. is adopted, this becomes a matter of less importance. Fruit tends to produce diarrhoea, and is seldom admissible. Wine, as advised above, is generally required, particularly when this stage passes into extreme prostration; and may be given in the nourishment adopted, or in soda water, Seltzer water, &c., diluted with warm water, or with tepid fresh whey. If brandy be used, it may be given in the same vehicles, or in weak black tea, in a state of much dilution. In the true typhus, stimulating the external senses is more necessary in this stage than previously; and it is often beneficial, as HILDENBRAND and NAUMANN advise, to rouse the patient's moral sentiments and affections, and to disperse his fugitive and chaotic ideas, by recalling former associations and objects of affection or of ambition. In extreme cases, however, the physical powers should be excited at the same time as the moral; otherwise the latter will be appealed to in vain. In a case of putro-adyamic fever, in which I took great interest, these united means proved successful in rallying the energies of life, under peculiarly unfavourable circumstances. During an expected crisis, a greater warmth of the bed-clothes is proper, and warm whey or other appropriate fluids should be given to encourage salutary evacuations (§ 167.).

615. *c.* During the *abatement* of the disease, the importance of diet and regimen increases, as treatment by medicine is now gradually abandoned. Nourishing food of easy digestion, taken in small quantities; pure air, and wine in some cases, are generally required; but these should be strictly prescribed as to kind, quantity, and frequency, according to the peculiarities of the case. As *convalescence* becomes established, the animal broths and soups may be succeeded by a

little solid animal food, of the lightest kind. The dangers to be apprehended during recovery have been fully stated above (§ 168.), their causes assigned, and the means of preventing them pointed out (§ 169.). Little further is, therefore, now required. But it will be most useful to recollect, that the management of convalescence should have some reference to the particular form and complication of the disease. In the exanthematic typhus, the danger of consecutive disorder is the least, particularly if it have run its course regularly and terminated by crisis. After low, nervous, and putro-adyamic fevers, affections of the brain, liver, bowels, lungs, and mesenteric glands, are not unusual, particularly when the patient has been prematurely exposed to changes of weather, to irregularities of diet, &c., and when the treatment has been injudicious, during early convalescence, or too soon relinquished. In all the varieties, the risk of these affections is increased by the complications which the fever presented; the organ which was prominently deranged remaining longer weak, or more susceptible than others of being disordered by excitation or by injurious agents. Therefore, in cases where the predominant disorder has been expressed on the encephalon, particular care should be taken to preserve the sensorial functions from early excitement or irritation, or undue exercise. Where the respiratory organs have been much affected, premature exposure to cold, or to changes of temperature, &c. ought to be guarded against; and where the digestive organs have manifested the onus of morbid action, the return to a full or stimulating diet should be long delayed, and the most digestible food only ought to be taken, and in moderate quantity. (See further on this subject, § 167—170.; and art. DEBILITY, § 36—46.)

FIBROUS TISSUE — ALTERATIONS OF THE. CLASSIF. — SPECIAL PATHOLOGY — *Morbid Structures.*

1. i. OF THE FIBROUS SYSTEM GENERALLY. — *A. The Fibrous System* consists — 1st, Of *fibrous membranes — membranæ fibrosæ* — as the periosteum, the cerebral and spinal dura mater, the fibrous capsules, the sheaths of tendons, aponeurotic expansions, the sclerotica, the capsule of the corpora cavernosa penis and of the clitoris, &c., the tunica albuginea, and the membranes proper to the spleen and kidneys; — 2dly,

Of *fibrous cords* in which the fibres are formed into fasciculi — *organa fibrosa fascicularia*. — Several of the former should be viewed as compound structures; as the dura mater, the tunica albuginea, the fibro-synovial sheaths, &c.; but the fibrous tissue constitutes their chief basis. With the exception of the fibrous membranes of a few glandular organs, it is easy to demonstrate that all the fibrous structures are connected together, and that the periosteum is the centre and basis of connection. This tissue consists of whitish, or greyish, shining, satiny, fibres of great fineness and strength. These are interwoven in various directions, in the first division of this tissue; and are placed parallel and very close to each other, in the second. Their cohesion is very great. Hence the fibrous tissue is the strongest in the body. Although it must be inferred to possess vessels and nerves, yet neither have been actually traced into it. That it is endowed with vital properties cannot be denied; but it manifests them obscurely in health, but often very remarkably in the course, or as a consequence, of certain diseases. Its physical properties are most perfect when the powers of life are energetic, and are much impaired when these are depressed or exhausted. During prolonged debility, and in cases of extreme vital exhaustion, the cohesion of this tissue is diminished, and laceration or extension of it takes place with less violence. During constitutional disorder, or contamination of the system by specific maladies, and in the scrofulous or gouty diathesis, it often becomes the seat of morbid action, and then evinces vital properties in a most evident manner. Injuries and irritations of this tissue, particularly when the vital functions are impaired or disordered, are often the source of the most violent and dangerous affections. — The fibrous tissue, however, is, with the exception of the periosteum and the capsules of joints, not very prone to disease; and, even when these are affected, a scrofulous or syphilitic taint has been the cause.

2. *B. Leaving out of consideration the congenital alterations of this tissue*, I will briefly notice those changes of it which are usually the result of disease. — *a. Fibrous parts* are seldom thinner than natural, or atrophied. — *b. Thickening* is much more frequent, and is evidently the result of slow inflammatory action. — *c. They* may also be expanded or distended by morbidly increased bulk of the organs which they envelope. We occasionally meet with this change in the fibrous coverings of the spleen, kidneys, articular capsules, &c. When the expansion arises from the accumulation of fluid, it is generally attended with thinning; and then, in some cases, the distension is chiefly in one part only, in the form of a sac, or is irregularly elongated. But the expansion may also be conjoined with thickening, as when it has proceeded from the changes consequent upon an inflammatory state of the contained parts in which the fibrous envelope itself had participated, as in diseases of the spleen, &c. — *d. The articular ligaments and capsules*, however, are frequently elongated and expanded without any internal change, and merely from diminished tone or vital cohesion — in some cases so much so, as to give rise to dislocations. — *e. Fibrous parts* may be also too short or too narrow. *Morbid contractions* are observed in tendons and

ligaments, and are generally the result of inflammatory irritation consequent upon great extension, cramp, &c.—*f.* The changes of colour met with in this structure are generally associated with change of organisation, excepting in jaundice. The morbid colours most frequently observed, are various shades of yellow, seldom brown, and rarely black, as in melanosis.

3. *C.* The continuity of this structure is sometimes destroyed; but generally from wounds, sudden extension, as in dislocations, and external violence of any kind. Continuity may likewise be destroyed by purulent collections, by tumours, and various morbid depositions between its fibres; but there is here, with a few exceptions, rather an expansion of the structure than actual breach of continuity. Incised wounds of this tissue heal in general with tolerable ease, in a healthy state of the system. But this is by no means the case when the habit or constitution is in fault, or when there is obvious disorder of the stomach and liver; and the difficulty is still further increased if the injury is attended with loss of substance, or when the tissue is lacerated. In these latter, the continuity of structure is in some measure supplied with cellular tissue, which becomes very dense by degrees, but never altogether tendinous. Hence the disposition to rupture or dislocation that exists so long, and indeed ever after such accidents. The chief exception to this is presented by the periosteum on some occasions, where it seems to have been quickly restored.

4. *D.* The texture of fibrous parts is changed generally by inflammation and its effects. But this disease is not frequent in fibrous structures, excepting the periosteum, the articular ligaments and capsules, and the dura mater.—In all these parts, however, it more frequently follows external injuries, than arises spontaneously. When it is spontaneous, it is almost always merely a concomitant of other diseases of a constitutional kind, such as *scrofula*, *syphilis*, *gout*, and *rheumatism*. The inflammation of this structure is rarely of an acute kind, excepting in some forms of gout and rheumatism; and in these the inflammatory state is consequent upon, and subordinate to, a morbid condition of the organic nerves, rather than identical with that which is caused by external injuries, or which assumes the phlogistic character. These specific forms neither pass through the same phases, nor terminate, as common phlogosis. The inflammation, also, proceeding from the scrofulous and syphilitic taint possesses the characteristic features of those specific diseases.

5. *a.* The course of inflammation is much more frequently slow; and often the phenomena are so indistinct, as to be overlooked. The changes thereby induced are generally co-ordinate with the activity and degree of the inflammatory action. *Redness*, in various degrees of depth, and attended with different states of vascular injection, is usually present. In some cases, there is a diffusel rose-red, especially when the inflamed tissue has access to the air. In others, more or less large and numerous red spots or irregular streaks are observed. In many, the inflamed part has a more or less yellowish colour; and if it be naturally glistening, this appearance is entirely lost. After chronic, or often-repeated attacks of inflammation, other discolourations are sometimes

remarked—the parts being either dark grey, brownish, livid, or even blackish.

6. *b.* *Swelling* is seldom remarkable in inflamed fibrous structures. But if the inflammation continue long, or if it recur frequently without complete resolution, fibrous organs, or the cellular tissue surrounding fibrous structures, are generally greatly swollen, and their boundaries indistinct, with a gelatinous fluid infiltrated into the adjoining texture, giving it a reddish, soft, and oedematous appearance. When the intensity of the inflammation is very high, it runs tediously into suppuration; the swelling and oedematous infiltration of the adjoining cellular substance at first increases, whilst the fibrous tissue wastes, the effused fluid, at various points, afterwards assumes a puriform appearance, increases, is concentrated, and at last more or less destroys this structure, the swelling at the circumference of the part becoming somewhat diminished.

7. *E.* *Ossification* is frequently observed in the fibrous structure, particularly in the ligaments and dura mater, and less frequently in the periosteum, the tendons, the fibrous membrane of the spleen; and but rarely in the other parts of this system. It is to be viewed as a consequence generally of slow inflammation, and occurs in different forms: as in some cases only the fibro-cartilaginous base of bone is deposited in plates or roundish flat prominences; more frequently phosphate of lime is secreted either in distinct spots or small masses surrounded by a circle or plexus of vessels, or in the form of splinters, or, lastly, in larger masses, involving the fibrous tissue equally throughout. If the articular ligaments undergo this change, they are then usually *shortened*, occasioning *stiffness* of the joint, or more or less complete *ankylosis*, according to the extent of the ossification. An *earthy mass*, less resembling bone than chalk or gypsum, consisting principally of the urate of soda—*gout tophus*,—is often deposited in the ligaments, in the neighbouring aponeurosis, and periosteum of one or several joints, in gouty persons, at first in a soft state, but gradually becoming hard, and often in large quantity.

9. *F.* *Sphacelation*, or *gangrene*, rarely occurs as a termination of inflammation. It is met with primarily in those fibrous parts which are well supplied with blood-vessels, viz. the periosteum, dura mater, fibrous envelope of the spleen, &c. In the tendons, aponeurosis, and articular ligaments, it very rarely occurs primarily, excepting when they are exposed to the air by wounds or ulcers, in which case they often are destroyed and exfoliate, together with the surface of the bones and cartilages. Fibrous structures, however, are often attacked with mortifications in conjunction with, or in consequence of, gangrene of the adjoining parts. Anthrax sometimes extends to and destroys fibrous tissues; and when mortification attacks a limb, the articular ligaments participate so entirely, that a spontaneous separation often takes place at a joint. *Exfoliation of tendons* may occur in whitloes, or during suppuration from punctured or poisoned wounds, as in dissection, &c. I have seen three such instances. *Fungus hamatodes* seated in fibrous parts is not rare.

9. *G.* *Adventitious productions* are but rarely observed in the fibrous system.—*a.* *Encysted tumours* seldom form in it, if we except those bursal tumours which occur on the tendinous

sheaths and articular capsules, and partly between the tendinous fibres of the aponeurosis, and especially on the elbow-joint and knee-cap, and which have their origin in the mucous bags placed in these situations.—*b. Tubercular formations* are equally rare in fibrous parts. Scrofulous deposits are, however, occasionally found in the dura mater and periosteum.—*c. Sarcomatous and fungous tumours* are more frequent in fibrous structures, particularly in the periosteum. Fungous growths on the tendons are more rare, as are the sarcomatous swellings upon the articular ligaments.—*d. Carcinoma, or cancer*, does not occur primarily in this system, but attacks it secondarily equally with other parts.

10. *H. The changes observed in the contents of cavities formed by fibrous membranes* are frequently marked and important. Morbid collections, as a watery serum, a gelatinous fluid, puriform matter, blood, &c., are not infrequently found in the aponeurotic sheaths surrounding or separating the muscles in the cavities of joints. The *synovia* also varies exceedingly; sometimes it is deficient in quantity, so much so as to occasion stiffness, creaking or a peculiar noise of the joint. More commonly it is in unusual quantity, particularly in all inflammatory states of the synovial membrane, but occasionally without any distinct inflammation, as in the knee-joint, in rheumatic, rickety, or syphilitic subjects. Sometimes the effusion exists to such a degree that the joint is more or less swollen, or even dislocated, or its use prevented. This local state of disease has usually been called *dropsy of a joint*, *hydrops articulo-rum*, *hydrarthrus meliceria*. The *synovia* is occasionally turbid, reddish, watery, albuminous, gelatinous, &c., as well as increased in quantity.

11. *I. Substances adventitious to the situation* have occasionally been found in the cavities of joints.—*a. Blood* is rarely observed; but—*b. Pus* occurs more frequently, it either having been produced within the joint itself, from an acute inflammation of the synovial membrane, and of the bony cartilages and ligaments forming the joint, or having made its way into the cavity from without. I have, however, seen cases where pus has rapidly collected in one or more joints after *phlebitis*, or after the absorption of this fluid from other and distant parts. It has been supposed that the pus, in such cases, has been secreted or deposited in the cavity of the joint, as it has passed into the circulation from the situation where it was primarily formed, without previous inflammation of the joint itself. But the presence of this morbid secretion in the blood may have excited inflammatory action of the synovial membrane, rapidly passing into the suppurative stage. In most of such cases, the parts containing the pus have been found eroded, and have presented other changes usually consequent upon inflammation, even when vascular injection has been absent. The question is, whether such changes have taken place previously or subsequently to the secretion of pus in the joint? That the more advanced of them are consequent upon the production of this fluid may be admitted; but that inflammatory injection and action preceded, and quickly produced the purulent collection, seems most probable.

12. *c. Cartilaginous concretions*, which have grown from the inner or expanded surface of the synovial membrane, by necked appendages, and been sub-

sequently broken off, are occasionally found in the cavities of joints, either entirely loose, or attached to them by thin threads. They are at first soft, then mostly cartilaginous, sometimes partly cartilaginous and bony; more rarely altogether bone; usually rounded, but occasionally flattened or angular; and varying much as to size and number. LIEUTAUD has adduced instances of *quicksilver* having been found in the cavities of joints; but such occurrences must have been rare, and are now never observed. (See art. PERIOSTEUM.)

13. *ii. INFLAMMATION OF THE FIBROUS STRUCTURE OF THE JOINTS* may occur primarily in this part, or extend to it from the lining synovial membrane, which, like other serous membranes, inflames readily, and in which the inflammation of joints most frequently commences. Inflammation of joints, implicating their fibrous structures, generally arises from external injuries, from metastasis of inflammation from other parts, from pus or morbid secretions absorbed into the circulation, from syphilis, gout, rheumatism, &c., and occasions reddening, swelling, softening, &c. of the synovial membrane. If the inflammation be not resolved, there is a consequent secretion into the cavity of the joint, sometimes of a fibrinous lymph occasioning ankylosis, but more frequently of a puriform matter, or of a fluid, which, after being retained there, assumes a puriform character, and which often softens or erodes the cartilaginous coverings of the heads of the bones. Frequently, also, inflammation of joints commences in the fine membrane lining the cartilages, or in the articular extremities of the bones themselves. This commonly occurs from the scrofulous and syphilitic taints, and gives rise to the *Caries articulo-rum centralis vel interna*, of RUST. When the disease originates in the synovial membrane or bones, the fibrous, fibro-cartilaginous, and even the bony parts of the joints themselves, are sometimes co-affected. This is especially the case, when the causes act violently on the joint, and affect equally all the tissues composing it, as after a violent injury, such as a penetrating wound, compound dislocation, or fracture extending into it. In all such cases, an acute and progressing general inflammation of the joint takes place, on which ankylosis, abscess, or caries, are usually consequent.

14. *A. In the scrofulous and rheumatic, however, a more undecided and chronic state of inflammation occurs, either spontaneously or from injuries, occasioning changes in the joints, which, according to their extent, seat, and symptoms, have been called morbus coxarius, hip disease, claudicatio or lameness, luxatio spontanea or spontaneous luxation, fungus articulo-rum, articular fungus, white swelling, &c.* However, with all these names, it is essentially the same disease. The joint is more or less remarkably swollen, less moveable than in the healthy state, and always somewhat bent. The swelling is, at certain parts, hard, firm, elastic; at other parts, more doughy, or even obscurely fluctuating. The integuments, to the last, even when sinuses are formed, remain unchanged, although sometimes slightly varicose, with a hardened state of the subjacent cellular and adipose tissues. The muscles surrounding the joint often appear pale and, together with the adjoining cellular substance, infiltrated with lymph. The articular

ligaments are more or less swollen, of a dull hue, frequently without any distinct fibres, hardened in some parts and softened in others, and often consolidated with the surrounding cellular structure. They are also whitish in some patches, and in others discoloured, generally converted into a mass containing minute cavities filled with lymph, a gelatinous fluid, or ichorous pus. The internal articular ligaments, the cartilaginous coverings of the bones, and the synovial membrane are entirely or partially destroyed. The bones either primarily or secondarily affected are, in a greater or less degree, inflamed, softened, swollen, and become internally carious; or they are but little swollen, tolerably hard, yet superficially eroded, or destroyed by caries. Owing to this carious state of the heads of the bones, whether attended with swelling or not, dislocation takes place. The articular cavity contains at first a large quantity of thickish, albuminous-like, often a pale reddish, synovia; and, in later stages of the disease, if the joint be more or less destroyed by suppuration, a thin, frequently foul-smelling, pus, mixed with blood, cartilage, and cartilaginous fragments, fill up entirely or partially the cavity of the joint (OTTO).

CLASSIF. — 1. *Class*, Disease of the Digestive Function; 1. *Order*, Affecting the Digestive Canal (Good). 1. *CLASS*, 1. *ORDER* (Author, in *Preface*).

1. *DEFIN.* — *An undue formation and accumulation of air in the stomach or intestines, with frequent rejection of it.*

2. It is of some importance to ascertain the source of the flatus which is often formed so abundantly in the digestive canal. JOHN HUNTER first supposed that air is sometimes exhaled from the blood by the vessels of secreting surfaces; and, if we view merely the results of the experiments of M. EDWARDS upon respiration, and the absorption and exhalation of various gases, by the lungs, in connection with the secretion of air into the swimming-bladder of fishes, this opinion will appear not ill-founded, even independently of the support it derives from pathological observation. In such cases we have reason to infer that it is not air, as it exists in the surrounding atmosphere, that is thus exhaled, but its constituent gases. The experiments performed by MM. GÉRARDIN, MAGENIE, and CHEVREUL have thrown much light upon the question as to the source of the gases found in the digestive canal, as well as upon their composition; and have shown, that they are partly exhaled from the digestive mucous surface. — It would appear, from the researches of these writers, that they consist, in the *stomach*, of nearly three parts in four of azote, the fourth part being oxygen and carbonic acid; and, in the *intestines*, of carbonic acid, azote, carburetted hydrogen, and hydrogen, in various proportions. It may, therefore, be inferred that the air which collects in the digestive canal is derived from three sources: — 1st. From the common air swallowed with the food; — 2d. From the changes or decomposition of the ingesta, and of the contents of the canal generally; — and, 3d. From the occasional exhalation of gaseous fluids from the mucous surface during certain states of local and constitutional disorder. The oxygen found in the stomach, amounting to eleven parts in a hundred, is most probably derived from the first of these sources. It is, however, either absorbed from this situation, or combines with other substances, as none is found beyond the pylorus. The azote and carbonic acid may be attributed partly to the last source; whilst a portion of both, and the whole of the hydrogen and its compounds, may be assigned to the second. — The air, which is generated so rapidly, and eructated so frequently, during acute inflammatory diseases, particularly in gastritis, hepatitis, &c., must be exhaled from the irritated mucous surface, inasmuch as there is no other source existing in such circumstances to which it can be attributed, especially when the constant vomitings, and frequent evacuations from the bowels, have left nothing in the *prima via* capable of furnishing the enormous quantity of air which is often ejected.

3. Flatulency, since the time of CULLEN, has been very generally viewed as a symptom of dyspepsia and of other diseases. But I agree with SAUVAGES, GOOD, and several other writers, in con-

sidering it to be occasionally a primary disorder. Whether it be idiopathic or symptomatic, its phenomena, and the disorders consequent upon it, are different according to the part of the alimentary canal in which the flatus is generated or confined. I shall, therefore, treat of this affection, *first*, as respects the stomach and œsophagus — *Flatulentia ventriculi*; and, *secondly*, with reference to the intestines — *Flatulentia Intestinorum*. But although it may be seated in either the stomach or the bowels more particularly, it very frequently exists in both at the same time.

4. I. FLATULENCY OF THE STOMACH will be considered at this place — (*a*) in respect of its idiopathic occurrence; (*b*) as a symptom of other disorders; and (*c*) with reference to the disturbances it tends either to induce or to aggravate. — *A. Primary or idiopathic flatulency of the stomach* is met with chiefly when the stomach is empty, or after the process of digestion in this viscus is completed; and is seldom associated either with impaired appetite, or diminished powers of digestion. It is most troublesome in the morning before breakfast, or during long fasting; or when an unusually protracted period has elapsed between meals. In such cases, the flatus often rises into the œsophagus, producing much uneasiness and often distress, owing to its excretion being prevented by the spasmodic constriction of the upper part of this tube. In swallowing also the more solid ingesta, the bolus meets the flatus in the œsophagus, and is interrupted or impeded in its passage to the stomach. In such circumstances, a conflict sometimes arises between the descending ingesta and the ascending flatus, and a very painful *spasmodic dysphagia* is thereby induced, until the eructation of air gives relief and allows the transit of the bolus into the stomach. In this form of the disorder, the air most probably is exhaled, at least in great part, from the internal surface of the organ. In other respects the patient's health is not deranged, and the functions of digestion, defœcation, and assimilation are regularly and perfectly performed. In other instances, slight defect of organic nervous power, owing to sexual indulgences, or to sedentary occupations, is the only pathological state to which this affection can be imputed.

5. *B. The remote causes of flatulency* are the nervous and hypochondriacal temperaments; and all the influences and habits which depress or exhaust the energy of the organic nervous system, or lower the tone of the digestive canal, especially sedentary occupations; excessive mental exertion and anxiety; venereal indulgences; intemperance in eating and drinking; the ingestion of cold fluids, particularly when the body is overheated; exposure to a cold air, or to cold in any way, whilst the stomach is empty, or whilst fasting; neglect of the functions of the bowels; the use of bulky or flatulent vegetables, or of fruits prone to undergo fermentation, especially cucumbers, melons, salads, &c.; irregularities of diet; and previous or existing disease. — Fast eating, and imperfect mastication, often give rise to flatulency, by the quantity of air which is generally swallowed on such occasions, and by the imperfect or slow digestion which usually results.

6. *C. Symptomatic flatulency of the stomach* is extremely common. — (*a*) It is almost a constant attendant upon *indigestion*; — and (*b*) often

accompanies general *debility*. — (*c*) It is also frequent in *hypochondriasis* and *mclancholia*; — and (*d*) in the numerous forms of *hysteria*. In this last, the flatus often rises into the œsophagus; and whilst the reaction of the coats of the stomach propels it into this tube, spasmodic constriction of the part just below the pharynx confines it for a time, and causes a distressing feeling of suffocation, &c. — (*e*) Flatulency is an almost constant symptom of *inflammatory* and *organic affections* of the stomach. — (*f*) It generally ushers in an attack of *gout*; — and (*g*) it both precedes and attends *asthmatic affections*. — (*h*) It is a common phenomenon of all the functional, inflammatory, and organic *diseases of the liver*; and is very characteristic of accumulations of bile in the gall-ducts and gall-bladder, and of *torpor of the biliary organs*. — (*i*) It often, also, occurs in the *functional and inflammatory disorders of the bowels*, and sometimes in affections of the other abdominal viscera. — (*k*) It not infrequently even accompanies *chronic diseases of the brain*; — and (*l*) the *adyamic and malignant forms of fever*.

7. *D. The phenomena* usually characteristic of flatulency vary somewhat with the diseases of which it is a symptom. In the course of digestion, flatus escapes with or without noise, and often with an acid, bitter, nidorous, or fœtid odour. Sometimes it is without either odour or taste; and at other times it retains the smell and flavour of the ingesta. When constriction of the cardia, or of the lower part of the œsophagus, prevents eructations, or when the coats of the stomach are so weakened, or so over-distended, as to be incapable of reacting sufficiently, *tympanitic* fulness of the epigastrium and hypochondria, with a painful sense of distension, or severe *gastrodynia*, frequent respiration, and heavy pain or oppression in the lower parts of the chest, are generally complained of. If eructations occur, especially for some hours after a full meal, acid or rancid matters, or portions of undigested food, are frequently regurgitated at the same time, and impress the palate and pharynx with an acrid and irritating sensation, or produce an unpleasant, dry cough, by affecting the epiglottis and larynx. *Cardialgia* is then often associated with this symptom, or precedes the eructations. When flatulency precedes or attends organic lesions of the stomach, or obstructions of the liver or pancreas, the symptoms caused by, and associated with, it are often severe. Disordered action of the heart, anxiety, hiccup, *gastrodynia*, &c., being not uncommonly observed.

8. *E. The disorders induced or aggravated by flatulency of the stomach*, are various in different habits and constitutions. When the stomach is much distended by flatus, and especially when the œsophagus admits and retains for a time the air in its lower part, the feeling of oppression, dull pain, and the other symptoms just mentioned, are much increased. The actions of the diaphragm are impeded, and the regularity of the circulation through the cavities of the heart is interrupted by the pressure of the over-distended organs. Hence the intermissions and irregularities of the pulse, the sense of anxiety, flutterings, feeling of suffocation, and palpitations, so often associated with, or consequent upon, affections of the digestive organs. *Wright* attributes *incubus* to flatulency of the stomach, and, I believe, very

justly. In delicate, nervous, and hysterical females, various symptomatic disorders, besides those now stated to arise directly from this cause, are often experienced. The modes of dress, particularly the very strait corsets used by this sex, aggravate the disorders consequent upon flatulent distension. — Severe pains of the left side, congestions of the lungs, or of the brain, headachs, convulsions, faintness, vertigo, and several anomalous complaints, often thus originate, not only in females, but also in males, especially those who are sedentary, hypochondriacal, and debilitated. In this class of persons more particularly, the pressure of the distended stomach prevents the due action of the bowels, and either impedes or interrupts the passage of fecal matters from the cæcum, along the transverse arch of the colon. — Thus costiveness, and functional disorders of the cæcum and large bowels, are occasioned, and are often followed, by displacement of parts of the colon, and by inflammatory and organic lesions. — It is obvious, that an aggravation of disorder will be occasioned by flatulence, where any of these affections already exist.

9. *F. Infants* are very liable to flatulence, particularly when their natural food is taken too greedily, or when it disagrees and becomes acid on the stomach. In some cases, a portion of air may be swallowed by sucking; but, however occasioned, the eructations that occur are often accompanied by the regurgitation of a considerable portion of the ingesta. Flatulence is, however, most distressing and injurious when it affects infants brought up without their natural sustenance, or during the period of weaning. In them, acidity of the prima via, watery diarrhoea, or costiveness, or both alternately, morbid offensive evacuations with severe griping pains, and emaciation, terminating not infrequently in marasmus and mesenteric disease, are often observed.

10. II. FLATULENCE OF THE INTESTINES may be either *primary* or *idiopathic*, or *symptomatic*, but most frequently the latter. — *A.* The *primary* form of intestinal flatulence is evidently itself but a symptom, if we trace the disorder up to its origin, or but one of the various phenomena resulting from debility of the digestive canal — from deficient energy of the ganglial nervous system. In this form, however, the flatus is either expelled from time to time, *per anum*, or accumulates and gives rise to borborygni or to tympanitic distension of the abdomen; but these symptoms seldom become very urgent in this state of the disorder, unless some other affection supervenes. The bowels are generally costive, sometimes irregular; and the secretions poured into the digestive canal, both from its own surface and from the collatitious organs, are deficient, and occasionally even morbid; the flatulence and imperfect functions of these parts being the almost coëtaneous effects of the impaired influence of the organic nervous system. The air which collects in this part of the digestive tube is to be ascribed chiefly to alterations of its contents, and to exhalation from the mucous surface. — This form of flatulence may continue long without any other material disorder, excepting slight debility, want of activity, costiveness, &c.; and it may occasion, in a short time, some one of the various serious diseases about to be noticed.

11. *B. Symptomatic intestinal flatulence* is a

common complaint. It is a frequent result of *costiveness*, or imperfect digestion in the bowels, particularly in the duodenum and cæcum; and of a deficient or morbid secretion from the intestinal mucous surface, and from the liver. When the quantity of air collected is great, colicky symptoms, obstinate constipation, and irregular action, or atony of the muscular fibres of the intestines, are the usual consequences. The coats being unable to contract regularly, or sufficiently to expel the air, or obstructions being opposed to the ejection of it, various effects of a serious kind often result. Portions of the bowels react with much violence upon the distending cause, whilst other portions are distended until the contractile power of the muscular coat is almost altogether lost. Thus spasmodic constriction in one part and paralytic distension in another are produced; and the organic sensibility of the nerves of the canal are remarkably excited or altered. Flatulent *colic* is the consequence; and if this be not relieved, intus-susceptions, ileus, or inflammation of a portion of the bowel, may ultimately supervene. If, in addition to imperfect or morbid secretion, the tone of the muscular coat is still further reduced — when its power of reacting upon the collection of flatus is lost more generally or completely, *meteorismus* or *tympanitis* will be produced, and the abdomen will be tense, painful, or tender, and the fecal evacuations either altogether suspended, or interrupted, and hard or scybalous.

12. Intestinal flatulence is a most common symptom in *hysteria*, and is in it generally indicated by borborygni, in *inflammations of the bowels*, in *dysentery*, in functional and organic *affections of the cæcum*, in *hepatic disorders*, especially *bilious colic*, in the *colic from lead*, and in the bowel complaints of *children*. It is very frequently met with in the advanced stages of *typhoid fevers*; and, as I have shown, it is one of the indications of extreme adynamia with predominant affection of the bowels. HIPPOCRATES remarks (*Coac. Prænot.* l. i. 46.), that inflation of the abdomen, without rejection of the flatus, is a dangerous sign; and the accuracy of the opinion must be admitted. In low fevers, the accumulation of air is often extremely great; and whilst it is an indication of danger, it tends to increase it by impeding the functions of respiration and circulation, as well as by exhausting the vital tone of the intestines.

13. *C.* Inflation of the bowels, particularly of the *colon*, gives rise to various symptomatic disorders, when it reaches a considerable height; and it not infrequently occasions the same affections as arise from flatulence of the stomach. Respiration and circulation are both often deranged by this cause; and congestions of the veins and sinuses of the brain consecutively induced. Hence vertigo and headachs often follow a sense of oppression in the chest, and irregularity of the heart's action. Hypochondriacal and hysterical symptoms are always aggravated by collections of flatus in the bowels; and these latter are favoured by costiveness. Hence the advantages resulting in these diseases from the use of stomatic of tonic aperients. — The colon may be also partially displaced, and adjoining parts injuriously pressed upon by collections of flatus in the large bowels.

14. III. Although flatulency very often is limited to either the stomach or bowels, presenting the pathological relations just explained, yet it also frequently extends almost simultaneously to both, or affects one or other more or less prominently. In this case, the effects produced by it will vary accordingly, and depend upon the degree in which it exists. — Flatus, moreover, is generated in other situations, as in the *uterus*, in the *urinary bladder*, and even in the *shut cavities*, but in very rare instances, particularly as respects the latter of these. In these parts, it is either exhaled from the vessels furnishing the secretions poured out on their internal surfaces, or developed in consequence of the changes which these secretions undergo during their retention. The formation of air in serous cavities is never, I believe, observed, excepting as a result of inflammatory action in some part of their surface that has given rise to a secretion of a sero-albuminous fluid; and it is not improbable that the air is produced by the partial decomposition of the albuminous portion of the secretion. These occurrences are more particularly noticed in other places.

15. IV. TREATMENT.—A. In the *primary states* of the disorder, attention to *diet*, and *gentle tonics*, with mild *aperients*, will generally restore the healthy functions of the stomach and intestines in a short time. If much distress be experienced from the retention of the flatus, the addition of a *carminative spirit* or oil, as those of anise-seed, pimenta, nutmeg, or cardamoms, to the above, will give relief; but the frequent use of heating spices may be injurious in other circumstances, particularly if the complaint depend upon chronic inflammatory action of the digestive mucous surface, as is frequently the case. The practice of rejecting the air, either upwards or downwards, should not be indulged in, for, although momentary relief is thereby obtained, an increased disposition to generate it is produced, and the evil augmented. It is only when air collects to the extent of producing much disorder, that its expulsion should be procured. — In this case, any of the numerous carminatives in common use may be given, if they be not contra-indicated by the presence of inflammation. In some such instances, however, the more energetic of them may be exhibited with advantage in enemata. The extract of *rue*, or any of the *essential oils*, may be thus prescribed.—HUFELAND and others advise warm dry *aromatic epithems* to be applied over the abdomen in these cases; and THUNBERG recommends the *cajuput oil* to be rubbed upon this part, or to be given internally, when the state of the circulation and of the animal heat indicates the propriety of exhibiting carminatives.—*Charcoal*, as suggested by J. P. FRANK, and *magnesia*, if not the most efficacious, are among the safest means that can be used. The same may be said of *camphor*, and the *terebinthinates*, and the plants which owe their efficacy to either of these principles. The *trisnitrate of bismuth* is often of great service, particularly when conjoined with small doses of *ipecacuanha* and *hyoscyamus*.

16. Whenever flatulency of the stomach or bowels is unconnected with inflammatory action — when the pulse is soft or weak, or not increased in frequency, when the abdomen and hypochondria are not painful on pressure, when the tongue is moist, or pale, and not red at its edges, and when

there is no unusual thirst — then carminatives, antispasmodics, stimulants, and tonics, combined with one another, and with absorbents and aperients, will give relief; and they may be either given by the mouth, or administered in enemata. — But even in these cases, our chief dependence should be placed upon suitable tonics, with the use of the cold salt-water bath, and attention to the secretions and excretions, for the cure of the complaint. — If an attentive view of the case suggests the existence of inflammatory irritation in any part of the alimentary canal, the *nitrate of potash*, and the *carbonate of soda* or of potash with *demulcents* or *emollients*, and weak camphor mixture, will be most appropriate. In these cases external *derivatives*, gentle frictions of the abdominal surface with warm *rubefacient liniments*, as recommended by WILLYT, the application of hot terebinthinate embrocations or epithems, or fomentations as used by DARWIN, will be of great service. When the complaint is connected either with slight inflammatory action, or with imperfect secretion, especially of bile; or with both, as observed in numerous instances; *deobstruents*, and *mild purgatives*, will be required. In such cases, the blue pill, or PLUMMER'S pill, or the hydrargyrum cum creta, ought to be given at bedtime, with soap, *ipecacuanha*, and taraxacum.

17. B. Flatulency in infants or young children ought to be treated chiefly by appropriate food and regimen, and by mild purgatives. *Magnesia in dill-water*, or in *fennel-water*, or in *anise-seed-water*, will frequently give relief; but an alterative, as the hydrargyrum cum creta, will generally be required on alternate nights. The warm or tepid bath, followed by frictions of the abdomen with some warm liniment; enemata with a little common salt, and some carminative water; and an occasional dose of castor oil, with warm clothing, and pure dry air, will also be productive of benefit.

18. C. In the more decidedly *symptomatic states of the complaint*, the treatment should be chiefly directed to the disease on which it depends. But in these states it is generally most urgent, and hence requires the adoption of means calculated to procure immediate relief. If those already described, employed according to the peculiarities of the case, prove inefficacious, it has been recommended by REICH, PAMAUD, THILLOW, and PLOIRY, to draw off, or to facilitate the escape of, the flatus, by a siphon, or by the introduction of a flexible hollow tube into the rectum. In most instances of difficulty, I have found the terebinthates with aperients, enemata with either spirits of turpentine or extract of rue, and terebinthinate embrocations or liniments applied to the abdomen, succeed in procuring the expulsion of the flatus, by exciting the action of the muscular fibres of the canal. — When this complaint depends chiefly upon debility, and is associated with other disorders proceeding from this source, the means advised in the articles COLIC, COSTIVENESS, and DEBILITY, according as it may present more or less of the features of either, should be prescribed; and *diet* and *regimen* ought to receive due attention.

FÆTUS — DISEASES OF THE.

CLASSIF.—GENERAL PATHOLOGY.

1. The *fætus* is liable to a greater number of diseases than has generally been supposed. Some of these, together with the lesions of the fetal appendages, have been noticed in the article ABORTION, § 10. As these diseases occasion various malformations, congenital alterations, abortions, or even the death of the *fætus*, a brief enumeration of them will be useful in various points of view, but particularly as indicative of the sources, in which several maladies of infancy originate.

2. i. The *Causes* of fetal disease are, as respects the *mother*—violent or prolonged mental emotions; imperfect or unwholesome nourishment; excessive fullness or deficiency of blood; a morbid state of this fluid, produced by food, medicines, or disease; alteratives, as mercury, &c., in large doses, or too long continued; attempts at procuring abortion; the use of strait corsets; injuries, falls, or blows on the abdomen; a cachectic state of constitution, particularly the syphilitic and scrofulous taints; constitutional or other diseases, as eruptive, periodic, or continued fevers, tubercular consumption, &c.; drunkenness and venereal excesses during pregnancy; a laborious life, or inordinate physical exertion, and previous lesions of the ovaria, uterus, or fetal appendages. The chief causes as respects the father, are, predisposing only, with the exception of the syphilitic or scrofulous taints. There is every reason to believe that, if the father is aged, or debilitated, or suffering from constitutional or local disorder, associated with sexual exhaustion, at the period when impregnation is effected, the *fætus* will be weakly formed, and thereby predisposed to disease, especially when the mother is exposed, during uterogestation, to the more energetic causes, or to those just enumerated.

3. ii. The *Diseases* observed in the *fætus*, either consequent upon one or more of the above causes, or occurring without any assignable cause, are—1st. *As respects the cerebra-spinal system*—effusions of fluid in the ventricles, or in the spinal canal, or between the membranes, giving rise to hydrocephalus, spina bifida, imperfect or arrested formation of portions of the brain or spinal cord, to inflammatory congestion of the membranes or

of portions of the brain or cerebellum (LOBSTEIN), with spasmodic contractions of the limbs, &c.;—2d. *As regards the thoracic viscera*—inflammation and suppuration of the thymus gland (VÉRON); tubercles in the lungs, in the early stages (BILLARD, LANGSTAFF, and myself), and in a state of softening (HUSSON); inflammation of the substance of the lungs, and of the pleura; dropsy of the pleural cavities; hydro-pericardium, and malformations of the heart;—3d. *As respects the abdominal viscera*—inflammation, and even ulceration, of the internal surface of various parts of the alimentary canal; tubercles in the liver (HOOGEVEN, HUSSON), in the mesentery (OEHLER), and in the spleen (BILLARD); inflammations of the liver (BRACHET, VÉRON); of one supra-renal capsule (ANDRAL), of the peritoneum (DESORMEAUX, VÉRON), of the small intestines (BILLARD); dropsy of the peritoneal cavity in various degrees (DUGÉS); enlargement of the mesenteric glands; accretions of the peritoneum, and of several viscera, from chronic inflammation (ANDRY, and myself); retention of urine, and excessive distension of the bladder, ureters, and pelvis of the kidneys, from obstructions to the discharge of it in the liquor amnii (SANDIFORT, MOREAU, PH. PINEL, A. COOPER, CHAUSSIER, DUGÉS, &c.); rupture of the bladder (DUGÉS); lesions of the kidneys, and other parts of the urinary apparatus (RUYSCH, HOFFMANN, WRISBERG, VROLIK, BOETSCHLER, DENIS, BOVIN, &c.); and obliterations of canals, and occlusions of their outlets, as of those of the alimentary canal, and of the urinary and generative organs;—4th. *As respects the general frame*—intermittent fevers, small-pox (DEUTTEL, &c.), and other eruptive fevers (ANDRY); syphilis, and jaundice (HEY, ANDRY, BAUMES, &c.);—and, 5th. *As regards external parts*—malformation of the palate, mouth, and lips; dislocation of various joints, and even of the hip joint (DUPUYTREN, CHAUSSIER, NORTH); contractions of muscles; fractures, gangrene, &c. of the limbs (JOERG); hardening of the cellular tissue (UZEMBEZIUS, MAURICEAU, STRATFORD, &c.); anasarca, and œdema of one or more limbs (GARDIEN, DUGÉS, ANDRY, &c.); hydrocele (ANDRY); various tumours and nævi; and several affections of the skin (GOECKEL, LEDEL, OEHLER, CHAUSSIER, ANDRY, &c.).

4. My limits prevent me from remarking upon these; but it may be mentioned, that MAURICEAU was born with the small-pox; and that jaundice may arise in the *fætus*—1st, from the same causes as induce it in the adult; and, 2dly, from jaundice in the mother. M. DUGÉS mentions that a lady was subject, during pregnancy, to colic and jaundice from biliary calculi; and, in four instances, the children were born deeply jaundiced. I attended, some years since, a lady in tubercular consumption, who was delivered, in the seventh month, of an emaciated and very small *fætus*, that died a few days afterwards. On examination, the lungs were founded loaded with tubercles, and the mesenteric glands enlarged. M. TONNÉ found an enormous fungoid tumour (*fungus hæmatodes*) on the right side of the head of a *fætus*; and M. VOISIN, a polypus adhering to the posterior part of the palate.—The existence of worms in the bowels of the *fætus* has been asserted by some writers, and denied by others. The evidence is not sufficiently conclusive either one way or another.

5. iii. The Death of the *Fœtus* may take place from the greater number of these diseases, or from lesions of the placenta, umbilical cord, or membranes (see *ABORTION*, § 10.). Although there are numerous exceptions to the rule, the more vigorous the *fœtus*, the stronger and more lively will be the sensations of its movement. It is evident that the existence, and far less the nature, of the *fœtal* malady cannot be ascertained before delivery; yet, in some instances, it may be suspected, from what is known of the causes. An attack of ague in the *fœtus* is usually made manifest to the mother; but does not generally cause abortion. The feebleness and slowness of the *fœtal* movements, after the fifth month, are indications of impaired strength of the *fœtus*, which should not be overlooked. The total cessation of motion; a feeling of uncomfortable weight gravitating to the side on which the patient lies, and of general uneasiness and coldness in the lower part of the abdomen; flaccidity of the abdominal parietes subsequent to a certain degree of tension; *fœtor* of the breath, pallor of the countenance, lividity of the eyelids or surrounding circle, and flaccidity of the breasts, generally denote the death of the *fœtus*; and when the pulsation of the heart cannot be heard on auscultation, this event may be inferred with certainty.

CLASSIF.—3. *Class*, Sanguineous Diseases; 4. *Order*, Cachexies (*Good*). IV. *CLASS*, IV. *ORDER* (*Author*, in *Preface*).

1. *DEFIN.*—A tumour, or tumours, consisting of a whitish, pulpy, brain-like substance; generally soft, circumscribed, elastic, or obscurely fluctuating; giving rise to large vascular growths, which bleed profusely: always connected with constitutional vice; contaminating the frame, and terminating fatally.

2. *i.* *DESCRIPTION.*—This is the most malignant formation to which the body is liable. When it appears covered only by the integuments, and has not yet acquired considerable bulk, the surface of the tumour which it forms is smooth, generally equal, and not discoloured; it is commonly soft and elastic, and communicates to the touch an obscure sense of fluctuation. When removed from the body, the hæmatoid tumour is generally circumscribed, and more or less rounded; it frequently possesses a capsule of condensed cellular membrane.—*A. M. LAENNEC* has divided the disease into—1st, the encysted; 2dly, the irregular and non-encysted; to which he has added, 3dly, the interstitial impregnation of organs by the cerebriform substance. This last is not mentioned by *Mr. WARDROP*, who has described this disease with great accuracy. *M. LAENNEC* has never met with it in the lungs. It may be, therefore, considered as a rare form of the disease. When divided, the substance soils the knife, and is composed of an opaque, whitish, homogeneous matter, resembling, in colour and consistence, the cerebral pulp. Hence the name, *Encephaloid*, given it by the French pathologists. It softens after exposure for a short time to the atmosphere; and when the softer part is washed away, or when the mass is compressed, a filamentous or fine cellular tissue remains.

3. *B.* The consistence of the hæmatoid tumour varies in different cases, and sometimes in different parts of the same mass—being sometimes more dense than the firmest brain, at other times as soft as the brain of a *fœtus*, as the milt of a fish, or even not much firmer than custard. According to *M. LOBSTEIN*, the different degrees of softening is owing to the progress of the disease; and this appears to be generally the case. In the first stage, or that of crudity, the melanoid tumour has the consistence of a firm brain, or of the conglobate glands; in the second, the consistence is less, being that of the *fœtal* brain; in the third, it approaches that of milt or custard: to these may be added a fourth, when the tumour is situated externally, or near the surface of an organ or part, viz. that attended with ulceration and the rapid production of bleeding fungi from the ulcerated part.

4. *C.* The colour of this production varies sometimes in the same mass. It is commonly of the colour of the brain; occasionally portions of it are redder, and exhibit more of a fleshy appearance; and in other cases, parts of it resemble a clot of blood. When the hæmatoid mass is encysted, it is readily detached from its capsule; and, in the early stage, is often divided into several lobes, placed closely together, and separated by an extremely fine cellular tissue, which seems to convey the vessels for its nutrition. In the advanced stages, the division into lobes disappears. The non-encysted form is, however, more common, particularly in the viscera. The masses constituting this formation vary from the size of a pea to that of the head of a *fœtus* at the full time.

5. *D.* The medullary structure, although the general, is not the only, form observed in the primarily diseased mass. Some of the fungoid productions are composed of distinct parts provided with cellular capsules, and differing in size, colour, and consistence. Some of these parts resemble slightly softened glue; others have earthy particles mixed with the pulpy cerebriform matter;

many present insulated portions of the colour and consistence of boiled yolk of egg. As the tumour increases, the softening and disorganisation characterising the successive stages of its growth takes place. Disorganisation generally commences in the central parts: cavities now form in it, chiefly containing blood; and, when the blood is washed away, and the tumour is placed in water, numerous membranous shreds and filaments are seen floating in these cavities.

6. If the fungoid mass is situate near the surface of any internal viscus, discolouration of, and adhesion to, the part covering it, followed by ulceration, take place. But the ulcerative process, instead of giving rise to loss of substance, produces a fungous growth, and, as well as when the tumour forms exteriorly, the increase of bulk, which had hitherto been slow, now becomes rapid. The fungus which thus forms is soft, easily torn, of a dark red or purple colour, of an irregular shape, and bleeds profusely when slightly injured; and differs from the firm dense structure of the cancerous fungus. It resembles, when small, the softer kinds of polypous vegetations which form on mucous surfaces.—When the primary hæmatoid tumours are situated towards the surface of the body, they increase in size more rapidly than when seated internally. They generally soon lose their uniform round and smooth appearance; they project very considerably, and at last become irregular at their surface. Their consistence diminishes, particularly in the projecting portions, where the soft elasticity passes into obscure fluctuation. The veins running over or from the diseased mass assume a varicose appearance; an erysipelatous-like redness of the prominent parts supervenes, followed by lividity, adhesion of the integuments to the tumour, ulceration, and soft reddish fungous excrescences. The growth of the tumour is now remarkably rapid. The surface of the fungi exudes a thin fetid sanies, often with blood, which is sometimes discharged in great quantity; hence arose the name *fungus hæmatodes*, which applies only to the advanced stage of the malady. When the fungus is very large, its more prominent parts often lose their vitality, and separate in most offensive sloughs.

7. In some cases the voluntary nerves have been connected with the diseased mass, and have participated in the change of structure; but they have not been found changed beyond the limits of the tumour. In the eye, the optic nerve is always changed in structure; and in a case referred to by Mr. WARDROP, the anterior crural nerve passed into the centre of the diseased mass, and was so completely lost in it, that it was impossible to distinguish between the two structures. This appearance being general whenever large nerves enter into the hæmatoid tumour, has led M. MAUNOUR to infer that the cerebriform matter composing it is nothing else than a morbid accumulation of the nervous pulp. This opinion is combated by M. LOBSTEIN, who avers that he has met with cases in which, particularly in early stages of the disease, the nerves passed through the tumour without experiencing any change. I am, however, disposed to doubt this, at least as respects the fully developed disease: if they pass through, I believe, from the dissection of a case which occurred to me, that they are always changed, and identified with the morbid mass:

if they pass merely *by it*, or between insulated portions of it, no change will be observed.

8. The most remarkable characteristics of this disease are—1st, The frequently simultaneous occurrence of a number of the tumours constituting it in different parts of the body; the least connected with each other, either by structure or function: and, 2d, That when an apparently isolated mass of the disease is met with in an extremity and extirpated, it always soon afterwards manifests itself in some distant part, either externally or internally; the subsequent disease being even more rapid in its progress than that preceding it. The simultaneous appearance of the hæmatoid tumours, or their successive manifestation, although sometimes observed to take place in the course of the absorbent system, seem not to be always propagated through this medium; for, in the case of the diseased mass appearing first in one of the lower extremities, the subsequent occurrence of it may not be in the glands above the originally affected part, but in some distant or internal organ, as in the lungs, liver, in an upper extremity, &c. This was well evinced in a most remarkable specimen of the disease which came before me several years since in a lad of about fifteen; who presented in all the extremities, upper and lower, in the parietes of the thorax and abdomen, in his neck and head, a number of those tumours, certainly not under fifty. They varied from the size of a walnut to that of a large orange; many of them were of simultaneous origin, and those which were the latest in appearing did not occur in the seat of the glands of the absorbents leading from the primary tumours. A somewhat similar, and still more remarkable case, in respect of the great extent and number of the tumours, both internal and external, I had lately an opportunity of seeing frequently with Mr. BUSHELL.

9. Often, however, when the original mass is advancing through the changes I have described, the absorbent glands become affected by the disease, and the internal viscera, and the whole constitution, are contaminated; or, perhaps, it would be more correct to say that the original contamination is thereby so far heightened as to occasion a more general formation of this diseased structure. When the absorbent system is affected, Mr. WARDROP states, that usually one or more glands swell in the vicinity of the primary tumour, and that this takes place sometimes at an early period of the disease, and occasionally not until the primary tumour is far advanced. In some cases the diseased glands grow to a great size, whilst in others they are but slightly enlarged. Occasionally the primary affection makes little progress, whilst the disease of the glands advances rapidly.—The structure of the glands thus secondarily affected is entirely converted into the cerebriform matter, exhibits a homogeneous pulpy mass, and is contained in a cellular capsule. Mr. WARDROP has never observed a fungus arise from the diseased gland.

10. This morbid production may appear in one part only, or in several at the same time, or in distant parts successively. The tumours which first appear may be called *primary*; those which occur afterwards, either in the absorbent glands or in remote parts, may be named *consecutive*. But the disease may terminate fatally without any more than a single mass being developed.

Mr. LANGSTAFF has adduced an instance of this. The primary tumour may be small, and the subsequent productions most extensive, or the reverse.

11. There is scarcely any organ or part of the body exempt from this disease. The extremities, the mammae, thyroid gland, the testes, ovaria, uterus, the lungs, the liver, pancreas, spleen, the stomach, the intestines, the urinary bladder, prostate gland, the mesentery, omentum, the eye, the brain, the spinal cord, the nerves, the glands, the heart, the muscular parts of the trunk, the bones, &c., have all been found affected with this malignant disease. It seems to commence in the cellular tissue; but, as it is developed, the proper texture of parts to which it extends is either converted into it, or is absorbed in proportion as it is increased.

12. ii. PROGRESS AND DURATION.—*a.* The progress of the disease may be divided into four stages.—In the *first*, the tumour has the consistence of the conglobate glands; in the *second*, it is much softer; in the *third*, the softening is still greater, and amounts to a state of semi-liquefaction, and gives the sensation of fluctuation; in the *fourth*, ulceration or vascular fungi arise.—Signs of general cachexy appear in the second or third stage, and are very decided in the fourth.—*b.* The duration of this malady is generally some months at least; and it may continue for two or three years. In the early stages, it is not usually attended by febrile action, or much pain; and it may exist for a considerable time without occasioning emaciation; but there is always more or less debility. Acceleration of pulse, and emaciation, appear in the advanced stages, often accompanied with effusion into the adjoining cavities, particularly when an internal organ is the seat of the malady, as the liver, uterus, &c.—In the *third* and *fourth* stages, the vital functions are very manifestly affected. The stomach loses its power, or rejects the ingesta. The patient experiences most severe pain; and the energies of life decline. The complexion often assumes a livid, earthy, or peculiar yellowish hue, or pale straw colour; the pulse becomes smaller and weaker; and at last the patient sinks, generally without either delirium or insensibility having existed for any considerable time before death.

13. iii. DIAGNOSIS AND COMPLICATIONS.—This disease was confounded with cancer until the commencement of this century, when BURNS and HEY first remarked the difference between them. They are still considered by some Continental pathologists, and by Dr. CARSWELL, as varieties or modifications of the same constitutional malady; and there are several circumstances which both favour and militate against this opinion. They both occur in similar habits of body and temperaments; they often arise spontaneously, or without any manifest cause, or are traced to the same exciting agents; they are both dependent upon constitutional vice, as well as upon perverted organic action and secretion in their seats; and they both undergo somewhat similar local changes, and occasion an increasing contamination of the fluids and soft solids. Moreover, as I have stated in another place (see article DISEASE, § 141—144.), and as Drs. KERR and CARSWELL have justly remarked, both may co-exist, or the carcinomatous may pass into the fungoid formation. Dr. CARSWELL observes, that numerous examples

might be given of scirrhus, medullary sarcoma, and fungus hæmatodes, as they are commonly called, originating in the same morbid state, and passing successively from the one into the other in the order in which they have been named. Indeed, these varieties are sometimes met with not only in different organs of the same individual, but even in the same organ.

14. The points, however, of dissimilarity are very striking, as remarked in the article referred to (§ 141—144.); and, notwithstanding these circumstances, are sufficient to constitute them distinct diseases. As these points have not been brought into view by the able writers just mentioned, and as they deserve a fuller notice than I have bestowed on them in the sketch indicated above, I shall here state them more fully.—*a.* There is no relation between the hard, incompressible texture of scirrhus, in which carcinoma commences, and the cerebriiform, elastic, and soft substance constituting fungoid disease.—*b.* Carcinoma commences in scirrhus, which confounds in one mass all the tissues which it invades, and often without much increase of bulk, although with augmented density; fungoid disease always consists of a more or less evident tumour, which seems to destroy every trace of any other structure.—*c.* Carcinoma, even in an advanced stage, when fungous projections sprout from its ulcerated parts, presents but little vascularity; whereas the fungoid disease possesses large vessels and vascular cavities, so that it derives one of its most common names from this circumstance.—*d.* Fungoid disease attacks organs in which true carcinoma has not hitherto been seen to originate; as the lungs, the liver, the brain, the spinal cord, and the nervous trunks.—*e.* Cancer affects the aged, fungoid disease the young; and the former is attended with more pain at the commencement than the latter:—and, *f.* as, MM. MAUNOIR, LOBSTEIN, and VELPEAU have remarked, there is something peculiar in the cachexy attending carcinoma, that is not observed in the fungoid malady; for it is not unusual to see persons, labouring under this latter affection, possessing their natural colour. This, I believe, occurs most frequently when some external part only is affected, or when the disease has not invaded the digestive or assimilating organs, or when absorption of the morbid matter has not taken place to a great amount. In a case now under my care, the healthy complexion is preserved, and yet neither the able practitioners who have seen it, nor myself, have any doubt as to its nature.

15. M. LOBSTEIN asks, with reference to the question of the identity of these two maladies, whether, admitting that true cancer sometimes gives rise to the fungoid formation, it therefore follows that this latter is the same as cancer? May there not exist, simultaneously, tuberculous degeneration of the lungs, fungoid disease of the liver, and fibrous tumours in the womb, without inferring the identity of these three morbid formations? Fungoid disease, therefore, appears, from its vascular relations, from its peculiar structure, and from its early characters, its advanced course and terminations, to be a distinct malady, although it may be consequent upon, or complicated with, other alterations of structure. When it occurs in young subjects, it is always *primary*, or is not

preceded nor attended by the carcinomatous formation. But in persons past the meridian of life, in whom only scirrhus-cancer or carcinoma is met with, the fungoid structure is sometimes produced *consecutively*, or in an advanced stage of it, and thus occasionally exists as a secondary complication with that disease, or as one of the advanced changes of structure consequent upon the constitutional vice. The question, therefore, as to difference is reduced to this,—that, when fungoid disease attacks young persons, it is always a primary and distinct malady; and that, when it affects persons advanced in life, it is either primary, or consecutive of, and complicated with, carcinoma (see art. DISEASE, § 141—144.). In a few instances, other morbid formations besides this have been found associated with the cerebriform structure, as fibrous tumours, scrofulous matters, pus, melanosis, hydatids, osseous and earthy deposits, &c.*

* Besides the distinctions I have insisted upon above, SCARPA and BEARD have added others, which I may here notice at length. The cerebriform or fungoid structure, when fully developed, is a milk-white pulpy substance, studded with rose-coloured points—scirrhus-cancer has the appearance of the skin of brown, and is traversed by numerous cellulo-fibrous radii or bands. The former comprises a number of arterial vessels, that increase with the softening which it undergoes; extravasations of blood take place in its substance; and the ulceration of its advanced stage is accompanied with hæmorrhage, which is often repeated, and frequently profuse;—the latter is nearly deprived of vessels; sanguineous extravasation is seldom observed in it; and the ulceration to which it gives rise is rarely attended by any considerable hæmorrhage. The cerebriform substance is often found in the veins of the diseased part—sometimes nearly filling them—and occasionally, also, in those in the vicinity;—a similar circumstance is very seldom observed in scirrhus-cancer. The cerebriform disease attacks primarily all the systems, tissues, and organs of the body; the primary seat of carcinoma is much more limited. The former attains a great size, is lobulated, and presents a characteristic elasticity and softness;—the latter never reaches a great size, it even sometimes assumes the appearance of diminished bulk, with increased density, and has neither a rounded outline nor elasticity.—Fungoid tumours frequently co-exist, even primarily, in several organs—occasionally in considerable numbers;—carcinoma is generally solitary. The cerebriform disease softens into a rose-coloured *bouillie*; scirrhus assumes the form of a *jelly*. In their progress to the surface, the first stretches to the skin, and renders it thinner, without adhering to it; the second cements itself to the integuments, which no longer admit of motion, but are firmly attached to the diseased mass. The progress of ulceration in this is remarkably slow; in that very rapid. In the one, the period which elapses from the commencement of ulceration is often as long or longer than that which preceded this change; in the other, the period subsequent to ulceration is disproportionately short, and the lesions consequent upon it are of a much more acute and violent character, though the pain may be less.

It is in the early stage, or state of crudity, that these two maladies are distinguished from each other with greatest difficulty. The fungoid structure has not then attained the white colour it subsequently acquires. It is at first semi-transparent, firm, and divided into numerous lobules. Its vascularity is also not so great as at an advanced stage. But, although it thus resembles scirrhus, to conclude from this, that they are identical diseases, is to admit that the same lesion will give rise to two kinds of structure that essentially differ. But this stage of fungoid disease is very short; and in cases where a number of tumours are developed in different parts of the body, they all have the same cerebriform structure. Malignant disease may, however, present the *complicated* states above mentioned; the same tumour consisting partly of the carcinomatous and partly of the cerebriform structure. In addition to these, it may even comprise other morbid products, disseminated through it, or collected in one or more places.—In one part an adventitious fibrous tissue, in another a fibro-cartilaginous formation, in a third tubercular matter, in a fourth multilocular cysts containing various substances—here a gelatinous secretion, there a milky fluid, this a reddish or bloody matter, that an osseous or a cretaceous deposit. These, as well as the cerebriform products thus accidentally or occasionally comprised in carcinomatous or

16. iv. CAUSES.—*a.* The *predisposing causes* of fungoid disease are—debility of constitution, early age, and peculiarity of diathesis. Children, and persons who have not passed the meridian of life, are much more frequently affected by it than persons in the decline of life. Those of the lymphatic and nervous temperaments, of a scrofulous constitution, of a sallow or pale complexion, and of a lax fibre, with a flabby state of the soft solids, and languid circulation, are oftenest its subjects. As to the influence of sex, sufficient data have not been furnished to admit of an opinion; but the most of several cases which I have seen have occurred in males. The same may be said of the influence of climate; but, like cancer, it seems to be most prevalent in countries the inhabitants of which partake largely of animal food. It has even been supposed that eating much pork predisposes to it. An hereditary disposition to it may be admitted with more truth. General debility is, however, its most common antecedent.—*b.* The *exciting causes* are often unknown. Sometimes an external injury, as a blow or bruise, has occasioned it, often after a long period. Most of the cases which I have seen appeared to have arisen chiefly from a poor and unwholesome diet, aided by cold and moisture.

17. v. The PROGNOSIS is extremely unfavourable. If the malady is developed so as to admit of precise recognition, a fatal issue may be delayed a short time by a tonic or restorative treatment, but can never be averted. Extirpation, or amputation, has been attempted, but with no benefit, and often with disadvantage. Although the diseased part be removed in this way, its source is still in the constitution, and it soon afterwards is developed in some other situation, generally in an internal viscus, the nearest to the seat of the extirpated part. If it exist also in an internal organ, the shock occasioned by the operation accelerates its growth and fatal progress.

18. vi. ORIGIN.—Many writers on this disease, and especially the French pathologists, suppose that the diathesis in which the disease originates is connected with the cancerous taint; and that the fungoid is only an advanced stage, or higher grade of carcinoma. MM. MAUENOIR and LOBSTEIN are opposed to this view; and my opinion, as just stated, coincides with theirs. Although both diseases are distinct as to the *kind* of action, as to the form of the morbid structure that results, and as to some of the circumstances in which it takes place, yet the *manner* in which they both arise may not be different; their morbid actions being similar in some respects, but different in others. Hence the alliance occasionally observed between them; as in other diseases generally connected, but specifically different. The opinion, therefore, which I have stated as to the origin of CANCER (§ 25, 26.), and the remarks there offered, are, in part, applicable to this disease.—Dr. HODGKIN has endeavoured to show that fungus hæmatodes and carcinoma originate in a cystiform serous membrane. That they thus arise in some instances may be admitted; but I agree with Dr. CAUSWELL in the opinion that they are often formed independently, and where

malignant tumours, are not the constituents of carcinoma, but contingent formations consequent upon the morbid nutrition and secretion constituting the local disease.

cysts cannot be detected; and that, even where cysts have existed, their formation in the cellular tissue external to the cysts has been demonstrated. — The views of M. ANDRAL have been stated in the article just referred to, and in that on DISEASE, § 138. M. CRUVEILLIER believes that this, as well as some other lesions, are the results of the deposition of morbid products in the cellular tissue of organs, the venous capillary system furnishing these products.

19. Dr. CARSWELL is of opinion that the formation of the fungoid and carcinomatous substance takes place in the blood, whether it be found in this fluid alone or in other parts of the body at the same time; and he adduces the facts — 1st, That the morbid substance is found in the vessels which ramify in these malignant tumours, or in their vicinity; — 2dly, That it is found in those vessels which communicate with the diseased part of an organ; — and, 3dly, That it is met with in vessels having no direct communication with an organ affected with the same disease. The veins, however, and venous capillaries, are the only parts of the vascular system in which the diseased substance is found — sometimes in contact with the internal surface of the vein, or occasionally united with it by means of thin colourless fibrine, or even of very minute blood-vessels, as in the case of the cerebriform matter. In the articles referred to, I have stated that, when this morbid substance is detected in the blood, it has been absorbed, as in the case of other morbid secretions; and the accuracy of the opinion seems to be supported by the fact, that it is found only in the veins and absorbents; but Dr. CARSWELL believes that this is not the case, as there are instances in which the venous blood alone was the seat of the disease. If such be actually the case, an obvious difficulty presents itself; but various sources of deception arise in the course of minute researches, and mislead even the most careful. That the blood is early affected in this and other malignant diseases, I fully believe; but that the cerebriform matter is formed in it, and afterwards deposited in the parts which are its seats, cannot be supported by the history and progress of the local and constitutional affections. If it were previously formed in the blood, wherefore is it often deposited only in one situation? — wherefore is it not excreted by the emunctories? — wherefore does it not always affect a number of parts simultaneously? — wherefore is it never found in the arteries, and so frequently in the absorbents and veins proceeding from the seat of disease? — These and other questions that may be asked, cannot be answered consistently with this doctrine. I therefore entertain the same opinion as was stated by me in the articles already referred to, and believe that, like carcinoma, it essentially depends upon a debilitated and otherwise morbid state of the system generally; and that the vital actions of the part or parts primarily and especially affected are depraved — that the nutrition, organic sensibility, and the secreting function of these parts are remarkably altered, and that the morbid product which results is partially absorbed into the circulation, and contaminates the fluids and soft solids, sometimes exciting a similar morbid action in other situations.

20. Conformably with the best ascertained facts connected with the appearance of the cere-

briform matter in the vessels, it would seem, that at a somewhat advanced stage of the disease, or when this structure becomes more or less softened, the molecules of it pass into the veins and absorbents leading from the part in which they have been formed; that they there sometimes are aggregated into masses sufficiently large to admit of their recognition; that, although these masses are generally found merely in contact with the internal surface of the veins, they sometimes adhere to it by means of the fibrine which collects around them, as in every other instance in which a semifluid or partially concrete substance, or a secreted matter of greater consistence than the blood, passes into the circulation; and that, when they thus adhere to the internal surface of the veins, minute vessels are ultimately developed in the fibrinous envelope which has been formed around them. — The principal changes observed in the blood of those affected by this disease, and which I have had an opportunity of remarking in two cases after death, are, an unusual thinness — a deficiency of fibrine and red particles — a state of partial anæmia — and imperfect coagulation. This state has been also remarked by BÉCLARD, VELPEAU, ANDRAL, and KERR, whose observations respecting the presence of the cerebriform matter, surrounded by a fibrinous envelope, in the venous blood, fully confirm the view I have taken of its origin in this situation, and militate against its primary formation in this fluid. (See articles CANCER, § 26.; and DISEASE, § 141.)

21. vii. TREATMENT. — This is a subject on which much cannot be said with any hope of advantage. Surgical treatment is of no avail, and strictly medical means of very little more. Whatever excites pain, or irritates the local disease, tends to promote its growth; and whatever lowers constitutional power, only lays the system more open to contamination. The intentions, therefore, which we should propose to ourselves, when entering upon the treatment of this malady, are — 1st, to support the powers of life, and thereby to resist as long as possible the extension of the disease; — 2dly, to promote the secretions and excretions, as auxiliary to the first indication; — and, 3dly, to palliate the sufferings of the patient.

22. A. The first of these is founded upon the evident and admitted fact that the disease is dependent upon, and associated with, debility; and upon the results of observation; and the means which may be employed to fulfil it need not be materially different from those specified in the article CANCER, § 29. *et seq.* Although no medicine has hitherto proved successful in curing the malady, yet new remedies, or novel combinations of those that are old, should nevertheless be directed against it. Besides, judicious means have often prolonged life, or enabled the system to resist its progress for a time. Conformably with these views, the preparations of cinchona; the sulphate of quinine; the preparations and compounds of iron, particularly the ferri ammonio-chloridum, and the tincture of the sesquichloride; sarsaparilla; bitter tonic infusions or decoctions, with liquor potassæ, or the alkaline carbonates; and the preparations of iodine, — may be severally used, and combined with some one of the more energetic narcotics, particularly the acetate or hydrochlorate of morphia, or conium, or belladonna, or aconitum. — The preparations of iodine

are the most successful of any means I have employed, in resisting the progress of this morbid formation. The ioduret or iodide of iron, and the iodide of potassium, should be selected, and taken internally in small or moderate doses. The external use of iodine is often injurious. In a case of this disease, affecting chiefly the stomach and some others of the abdominal viscera, lately under my care, a combination of the acetate of morphia and kréosote palliated the urgent symptoms after other means had failed. In the still more recent case of a lady from Wales, who came to town on account of malignant disease of the stomach, that probably partook of the fungoid character, from the size of the tumour and other symptoms, this combination proved serviceable. This lady had been treated with great discrimination by Mr. SERPH of Welshpool. During her stay in London, the acetate of morphia in a dilute aromatic spirit always afforded relief; but, when the disease had advanced further, and after her return home, it had but little effect. Mr. SERPH, therefore, at my request, gave her the following during the paroxysms of suffering, with great benefit:—

No. 27. R. Morphiæ Acetatis gr. ij.; Kréosote M xij.; Pulv. Glycyrrh. et Pulv. Acaciæ, aa q. s. ut fiat massa æqualis, quam divide in Pil. xij. Capiat unam, omni horâ, urgenti dolore.

23. When the diseased part appears about to ulcerate, and afterwards especially, it should be protected from external injury or irritation; and if the bleeding from it be copious, or the discharge offensive, a solution of kréosote in weak pyroligneous acid or spirits of turpentine will prove the most efficient styptic and corrigent. The chloride of lime may likewise be employed. In addition to the other tonics just enumerated, the chlorate of potash may be tried in the decoction of cinchona. If iodine be prescribed, it should be continued for a long time. The iodide of potassium may be given in the compound decoction of sarsaparilla; with conium, aconitum, or any other narcotic, if much pain be felt. During the course of treatment, the secretions and excretions should be regularly promoted; and if the bowels be sluggish, their actions ought to be promoted by a tonic or stomachic aperient repeated according to circumstances. The other means, which have been recommended in the article CANCER (which see), are equally appropriate in this, and other malignant formations.

FURUNCULAR ERUPTIONS.—*SYN.* *Furuncular Inflammations; Furuncles. Furunculi; Furunculus, Sauvages. Pnyma, Willan, Good. Phlysis Furunculosa, Young.*

CLASSIF.—3. Class, 2. Order (Good). 7. Order, 1. Genus (Willan). IV. CLASS, IV. ORDER (Author).

1. DEFIN.—*Inflammation of the cellular appendices penetrating the reticular texture of the corion, arising from disorder of the digestive organs, and modified in character by the state of constitutional power, and the condition of the circulating fluids.*

2. The true skin or corion is penetrated by small conical prolongations derived from the cellular tissue underneath. With these, the vessels and nerves proceed to the superficies of the corion to form the papillar tissue and vascular rete. When inflammation commences in one or more of these prolongations, furunculus or boil, hordeolum or sty, and anthrax or carbuncle, are the results; but in these, the surrounding true skin, with the subjacent cellular tissue, participate to a greater or less extent with the progress of inflammation. M. RAYER remarks, that, left to themselves, these affections always terminate in the mortification, and subsequent expulsion, of one or more of the small cellular cones of the dermal tissue, which are then designated by the title of cores. This termination is generally ascribed to the resistance offered by the fibrous corion to the expansion of the cone of inflamed cellular tissue, and to the consequent strangulation of it; but the cores are probably the condensed tissue surrounding the matter which is formed in the inflamed tumour, and which is thrown off after this matter is discharged. It is even possible, that the inflammation in this affection commences in the vessels themselves which accompany the cellular elongations or cones; and that the disease is actually a limited angeitis, or arteritis, of one small branch, the cellular substance sloughing in consequence of its supply of blood being cut off, from an impervious state of some of the minute ramifications.

3. The varieties of furuncle are generally dependent upon disordered states of the digestive functions, and the characters which they assume vary with the states of vital action and of the circulating fluids. When furuncle occurs in a tolerably sound constitution, and healthy condition of the blood, it assumes a *sthenic* character, and constitutes *furunculus* or the *common boil*, or *sty* when it is seated in the eyelid. But, when it affects the aged or debilitated, or previously diseased, or the cachectic, or those in whom the circulating fluids are impure, and the vital actions languid or imperfect, it puts on an *asthenic* form, and gives rise to two varieties; one of which has been noticed only by M. GUERSENT and myself, and which may be called *Asthenic Furuncle*; and the other has been usually named *Anthrax* or *Carbuncle*.

I. STHENIC FURUNCLE—*Boil; Furuncle; Phyma Furunculosa, Good; Furuncle, Clou, Fr.; Die Beule, Germ.*

4. This species is characterised by small inflammatory swelling of the skin and subjacent cel-

ular tissue; this swelling being circumscribed, conical, hard, red, hot, and painful; and terminating in the formation of a small quantity of matter, and the expulsion of dead cellular tissue.

5. i. *Symptoms.*—This affection begins in a small, hard tumour, most frequently seated on the hips, buttocks, thighs, back, nape of the neck, and armpits. The tumour becomes conical, painful, of a vivid or violet red colour, and reaches, in a few days, the size of a large walnut. From the fifth, to the eighth day, it points, the apex becoming white and soft. It soon afterwards breaks, and discharges a little sanguineous pus, the outer part of the slough being exposed through the small opening. The core or slough is generally expelled two or three days afterwards, and the pain then ceases, the swelling subsides, the cavity left by the core fills up, and, in a few days, the opening closes, a cicatrix only remaining. One boil is often followed by others, which follow a similar course, and attain various sizes. They may succeed one another more or less rapidly; but they are seldom attended by fever, unless they are large or numerous. When they form in the perineum, or near the anus, difficulty of voiding urine is often felt. In other situations, they may affect the lymphatics proceeding from their seats, and the adjoining glands.

6. ii. *Causes.*—The application of blisters, frictions with irritating liniments or ointments, inattention to personal cleanliness, the use of sulphureous or alkaline baths, and various antecedent or associated affections, are the usual causes of this eruption. Furuncle is often consequent upon the decline of, or convalescence from, fevers, the exanthemata, and inflammatory disease of the skin; and it often seems to depend upon weakness, or chronic inflammatory irritation, of the digestive organs; or upon the accumulation of sordes in the *prima via*. In some cases, however, it occurs without appreciable antecedent disorder.

7. iii. *Treatment.*—But little is required for this complaint beyond attention to the digestive organs. Accumulations of mucous sordes and faecal matters ought to be freely evacuated by an aperient consisting of equal parts of the compound infusions of gentian and senna with a neutral salt or alkaline carbonate. A bread and water poultice, or any other soothing and relaxing application, may be kept on the part. If the boil be large, and the pain considerable, the division of the skin, at the most prominent part, will be of service. When a succession of boils appears, an emetic may be given, and its operation promoted by the infusion of chamomile flowers. The above stomachic aperient may be afterwards continued daily, or on alternate days. If the eruption still appears from time to time, gentle tonics may be prescribed. Dr. FOSBROOKE recommends large doses of sulphuric acid. Mr. COPLAND HUTCHINSON informed me, that he found the liquor potassæ, or Brandish's alkaline solution, in any bitter tonic infusion, most beneficial in these cases. The extract of taraxacum may be added to a mixture or draught of this kind, and an alterative pill given at bedtime, and continued for some days.

8. II. HORDEOLUM—*Stye; Phyma Hordeolum, Good; Sclerophthalmia, Σκληροφθάλμια; Orgeolet, Fr.; Gerstenhorn, Germ.*—is a small inflamma-

tory tumour or boil in the free edge of the eyelids, most frequently near the inner angle of the eye.—

It is in every respect a similar affection to furuncle, the difference arising entirely from the nature of its seat. It is seldom larger than a grain of barley, and is generally smaller, as its name indicates.—Its causes, progress, and treatment are in all respects the same as those of common boil.—This, and the preceding variety of furuncle, are most common in young persons, just before or soon after puberty, and in adults who eat largely and take much spirituous liquors.—In scrofulous constitutions, and persons addicted to intemperance, they assume a chronic form. In such cases, local applications with camphor are of service.

9. III. ASTHENIC FURUNCLE.—*Atonic Furuncle; Furuncle Atonique, GUERSENT*—consists of a small circumscribed swelling of the skin, in one or several situations, with or without livid discolouration; followed by a very small purulent phlyctæna at the summit, and by softening, destruction, and large perforation of the corion underneath; and preceded and attended by much debility and low fever.

10. This affection was described by M. GUERSENT, in 1823; and early in the same year I saw two cases of it, with Mr. PAINTER, in a low street and ill-ventilated apartment in Westminster. Both occurred in unhealthy children in the same family, and terminated fatally. The bodies were inspected after death. Since then I have seen only three other cases; but I have met with others somewhat similar, consequent on the application of leeches.—All the instances which have occurred in my practice, as well as those seen by M. GUERSENT, were in children much weakened by previous disease; or in those affected by gastro-intestinal irritation, or by chronic disorder of the bronchi, or asthenic inflammation of the substance of the lungs. There have always been, both before and after the appearance of this eruption, well-marked symptoms of adynamia; and coma has generally come on before death.

11. i. *Description.*—This eruption appears chiefly on the trunk, the lateral parts of the neck, and insides of the thighs. In the cases which I have seen, the number of furuncles was considerable—not fewer than five or six; and, in two cases, there were about twenty. They commence in small, circumscribed, and hard swellings, of a livid tint, but sometimes nearly colourless. At a further advanced stage, very small purulent phlyctænae appear in their summits, that break, and leave the skin underneath of a greyish colour, softened, and perforated as in common furunculi. They discharge at first a serous, sanguineous, or ichorous fluid. The tumours soften and disappear; and the perforations of the corion enlarge rapidly, producing, in two or three days, holes in the integuments, varying from three or four, to six or seven, or even eight or nine, lines in diameter. These perforations are perfectly round; their margins are not elevated, nor thickened, nor injected; and they entirely resemble the holes made by a drill or auger. The cellular tissue is not thrown off in the form of a core, but is destroyed by a rapid ulceration, or phagedenic absorption. The bottoms of the ulcers have a greyish or sanious appearance, and are nearly dry. There is no discharge from them, nor have they any tendency to scab; and the perforations

of the integuments frequently proceed down to the muscles, or aponeuroses, the peculiar structure of which may often be seen at their bottoms. The skin forming their margins is pale and somewhat softened, and the cellular tissue immediately beneath the cutaneous margins is often destroyed to the extent of one or two lines. — In the variety of asthenic furuncle following the bites of leeches in cachectic and debilitated children, which is the most common, the perforations of the skin are at first triangular, but their progress is nearly the same as that of the spontaneous variety, and as they enlarge they became entirely circular. The ulceration attending upon the advanced stage of disease is seldom very painful. Having reached the extent just described, it remains stationary for a longer or shorter time, and in the more unfavourable cases shows no disposition to reparation. When it evinces a disposition to heal, the bottom is more moist, somewhat redder, and more vivid; the perforated margins of the skin become more closely connected with the subjacent tissues, granulations arise and elevate the bottom of the ulcer, and the perforation is lessened. Thus a depressed cicatrix is formed, as in other cases where the skin has been destroyed.

12. In the two cases, in which I had the opportunity of seeing the appearances after death, no attempts at reparation were visible in the ulcerated perforations, which went down to the muscles, as if the part had been removed by an auger. There was no injection or inflammatory appearances in the margins. The chief alterations were moderate emaciation, congestion, and injection of the membranes of the brain, with slight serous effusion; congestion of the substance of the lungs, with limited hepatization in an early grade; patches of injection in the digestive mucous membrane, other parts being pale; and enlargement of the mesenteric glands. M. GUERSENT has not mentioned the internal lesions he may have observed; but those just noticed throw not much light upon the affection, and are of frequent occurrence after other diseases. In most of the cases I have treated, there has been low nervous fever, with more or less manifest affection of the gastro-intestinal surface, or of the head or lungs. The perforations are always uniform in character, although varying somewhat in size: they are peculiar; and are hardly ever modified from the state above described. They appear analogous to the perforating phagedenic or atonic ulcers sometimes seen in the stomach.

13. ii. *Treatment.* — The means of cure should necessarily be directed chiefly to the constitutional disorder. This should be removed, by the preparations of cinchona; by the sulphate of quinine; by the mineral or vegetable acids; by camphor or ammonia; by the decoction of bark with nitre, and spirits of nitric ether; by the infusion of valerian or cascarrilla with the chlorate of potash, or chloride of ammonia, and chloric ether; by camphor julep with the chloro-sodiac solution; or by similar remedies, aided by means calculated to relieve internal complications, as alteratives, external derivatives, and mild stomachic purgatives. Neither leeches nor blisters should be applied, as the former are liable to multiply the perforating ulcers, and the latter are apt to produce sphacelation. The semicupium, however, with much salt and mustard in the bath

may be used. Removal to a dry, healthy atmosphere, or to the sea-side, or to an elevated situation, and light nourishment, are also beneficial. The most efficacious local applications are, the solutions of the chlorinated soda or lime, kréosote, the dilute acids, pyroligneous acid with camphor and kréosote, poultices of powdered bark, with spirits of turpentine, and the balsams and terebinthines, especially Peruvian balsam, or equal parts of it, or of copaiba, and of turpentine.

III. CARBUNCLE. — *Ανθραξ*, Hippocrates; *Anthrax*; *Carbo*; *Persicus Ignis*; *Carbunculus*, Celsus; *Phyma Anthrax*, Good; *Charbon*, Fr.; *Karbunkel*, Germ.; *Furuncular Anthrax*.

14. Carbuncle appears in the form of a *hard, painful, circumscribed tumour of a deep red colour, with a sensation of burning heat, terminating in gangrene*. M. RAYER states that it is an acute inflammation affecting simultaneously several of the contiguous cellular cones penetrating the reticulations of the true skin. It is not improbable that the vessels themselves, particularly the arteries, are more or less implicated in the inflammation.

15. i. *Progress.* — Anthrax occurs most frequently in the nape of the neck, or above the nape, on the back, shoulders, buttocks, thighs, and sides of the trunk. It often commences in a small tumour, of a few lines in diameter, the apex of which is sometimes covered with a sanguinolent vesicle. In other cases it is much larger from the beginning, and it then generally advances with greater rapidity. As it spreads, so it becomes more prominent and penetrates more deeply; and, in seven or eight days, it is often as many inches in diameter. Its colour deepens to a violet or bluish tint, and it is hard throughout, until the cellular tissue of the central parts passes into gangrene. Its base afterwards continues to spread, the circumference remains hard, and the centre softens, and fluctuates very obscurely. The heat is still burning, the pain is tensile, and both are now referred chiefly to the base of the tumour. When left to itself, the skin covering the anthrax becomes thin and soft after some days, and is perforated in several places. It then discharges a little bloody pus, or ichorous matter with small shreds of mortified cellular tissue. It occasionally sphacelates to a much greater extent, and its surface becomes dark, black, and insensible. For some days afterwards, new perforations are formed, through which whitish sloughs of cellular substance are passed. The openings enlarge or run into each other; give passage to a thick sanguinolent matter; and sometimes emit a fetid odour. The sloughs are at length detached, the discharge increases and becomes thinner, and the pain and heat diminish. When the destruction of the integuments is considerable, the superficial fascia are often denuded, eroded, and even perforated — the surrounding skin being livid, bluish, thinned, and partially detached from the parts underneath. If a favourable change in the part takes place, granulations appear; and a cicatrix, which is always irregular, depressed, and puckered, and continues long dark, or brownish red, is formed, partly by the ulcerated surface, and partly by the union with it of the loose flaps of skin.

16. The constitutional symptoms are generally severe, and often precede the local lesion. Indeed, anthrax rarely occurs excepting in habits

of body evincing more or less cachexy, with sanguineous plethora, and disorder of the digestive functions. For some days before its eruption, the patient complains of anorexia and increased disorder of these functions, and of lassitude, chills, or shiverings. With the development of the tumour, the febrile commotion increases, and presents the usual concomitants of inflammatory fever. If sphacelation take place, or if the ulceration be protracted, the attendant fever assumes gradually an adynamic character; and in delicate, old, or very cachectic persons, it is nervous or adynamic from the commencement.

7. Various internal affections may also be complicated with the external disease. Congestions or inflammations of the liver or of a portion of the lungs, enlargement of the spleen, and gastro-intestinal disorders, are the most frequent associated complaints. When anthrax is seated in the neck, cerebral symptoms are often present. If it occur in the lateral or anterior parts of the neck, dyspnoea, cough, headache, and even serious affections of the larynx or trachea, are experienced. If it take place in the parietes of the chest, the most severe pleuritic and pulmonary symptoms sometimes supervene, from the extension of the inflammation internally to the pleura, and thence even to the lungs. When it attacks the abdominal parietes, peritonitis has even occurred in a similar manner. Anthrax may also be associated with some other external eruption, especially with the common furuncle, which may either precede or accompany it.

18. ii. Causes.—Anthrax is most common in spring and summer, according to M. RAYER. It is certainly most frequent in persons past the meridian of life, and in females about the total cessation of the menses. High, rich, or gross living, with insufficient exercise, and a full, gross habit of body, predispose to it, and even more directly produce it.—Causes which derange the digestive and biliary functions, the application of acrid or stimulating matters to the skin, neglect of personal cleanliness, and the bites of insects, most commonly excite it. It is often a sequela of small-pox, measles, and typhoid fevers; and it is a common attendant upon plague, and sometimes even appears in the latter stages of the putro-adynamic form of typhoid fever.

19. iii. Diagnosis.—Carbuncle is to be distinguished from the common boil, by the latter having only a single opening, and being smaller and more conical; and by several occurring in succession. The former, on the contrary, is broader, less acuminated, is perforated by several openings, is darker, and more gangrenous, and is generally single when occurring as an idiopathic disorder. According to DUPUYTREN and RAYER, however, anthrax is a tumour formed by the conglomeration and confluence of several furuncles. Carbuncle has very generally been confounded with malignant pustule, or anthracion. The latter belongs to a different order of affections of the skin; and is described, as well as distinguished from anthrax, in the article PUSTULES.

20. iv. Treatment.—This should be commenced with the exhibition of an emetic, the operation of which may be promoted by a tepid infusion of chamomile flowers. A full dose of calomel and James's powder should afterwards be

given, and the free action of the bowels promoted by purgatives.—Whenever the pulse is strong, full, or hard, bloodletting, according to the age and habit of the patient, is requisite, particularly early in the disease.—Leeches ought also to be applied around the base of the tumour, and the bleeding from their bites encouraged by tepid fomentations. A repetition of the local depletions may be required even oftener than once.—Diaphoretics, with the potassio-tartrate of antimony and opium, if the pain and burning be very severe, should afterwards be given, and the bowels kept open by the occasional exhibition of a purgative. When the attendant fever is of a low form, or when gangrene has taken place, and suppuration continued for some time, especially when the patient is aged, of a cachectic habit, or is addicted to intoxication, or is greatly debilitated, the decoction of cinchona, with the alkaline carbonates; the sulphate of quinine with camphor; tonic infusions with hydro-chloric acid and chloric ether; and the means advised in putro-adynamic fever, should be prescribed, with light nourishment, wine, &c.

21. The local treatment should consist chiefly of refrigerant applications in an early stage of the swelling. Compresses moistened with equal parts of pyroligneous acid and rose-water, to which some camphor has been added, should be constantly applied from the commencement. They generally relieve the pain and burning heat. If the inflammation still proceeds, a crucial incision, completely across the swelling, and down to its base, as advised by DUPUYTREN and RAYER, should be made. This will give instant relief by the loss of blood, and by removing the strangulation of the vessels and cellular tissue. It also averts gangrene, facilitates a healthy suppurative action, and hastens granulation and recovery. The actual and potential cauterics formerly advised, are now rarely employed. Several American writers recommend the application of blisters over the swelling—the discharge from the surface favouring a return of healthy action in the diseased part.

22. When anthrax is complicated with any of the internal affections indicated above (§ 17.), the treatment ought to be decided and appropriate to the morbid associations, as the progress of the complication is generally rapid, owing to the unfavourable state of constitution giving rise to this kind of local disease.—During convalescence, sulphureous baths, and the aperient sulphureous mineral waters, with strict attention to the functions of the digestive organs, and to diet and regimen, are usually productive of benefit. I have found the following medicines of service, when the patient cannot resort to suitable mineral waters.

No. 228. R Infusi Sennæ Comp., Infusi Gentianæ Co., aa ʒ vj.; Sodæ Carbon. gr. xij.; Spirit. Ammon. Arom. ʒss.; Tinct. Cardamom. Co. ʒj. M. Fiat Haustus, alternis noctibus sumendus.

No. 229. Potassæ Bitart. in Pulv. ʒj.; Sulphuris Præcipitat. ʒij.; Confect. Sennæ ʒij.; Syrup. Zingiberis q. s. ut fiat Electuarium molle, cujus capiat Coch. j. minimum, horâ somni quotidie.

END OF THE FIRST VOLUME.

LONDON:

Printed by A. SPOTTISWOODE,
New-Street-Square.

BOOKS ON RURAL SPORTS, &c.

RONALD'S FLY-FISHER'S ENTOMOLOGY: With Observations and Instructions relative to Trout and Grayling Fishing. *Fifth Edition*, thoroughly revised by an experienced Fly-Fisher; the Plates coloured after improved patterns. 8vo. with 20 coloured Plates, 14s.

EPIHEMERA'S BOOK of the SALMON; comprising the Theory, Principles, and Practice of Fly-Fishing for Salmon: With curious Lists of Flies, coloured Plates, &c. Fcp. 8vo. 14s.

EPIHEMERA'S HANDBOOK of ANGLING; teaching Fly-Fishing, Trotting, Bottom-Fishing, Salmon-Fishing. With many Woodcuts. Fcp. 8vo. 5s.

The ANGLER and his FRIEND; or, Piscatory Colloquies and Fishing Excursions. By JOHN DAVY, M.D., F.R.S. Fcp. 8vo. 6s.

The CRICKET-FIELD; or, the Science and History of the Game of Cricket. *Second Edition*; with Illustrations. Fcp. 8vo. 5s.

The GREYHOUND: A Treatise on the Art of Breeding, Rearing, and Training Greyhounds for Public Running. By STONEHENG. With many Illustrations. Square crown 8vo. 21s.

The RIFLE and the HOUND in CEYLON. By S. W. BAKER, Esq. With numerous Illustrations. 8vo. 14s.

REMINISCENCES of a HUNTSMAN. By the Hon. GRANTLEY F. BERKELEY. With 4 Etchings by JOHN LEECH (1 coloured). 8vo. 14s.

PRACTICAL HORSEMANSHIP. By HARRY HIEOVER. With Two Plates. Fcp. 8vo. 5s.

Captain RICHARDSON'S HORSEMANSHIP for the SCHOOL, the ROAD, and the FIELD; or, the Art of Riding and Managing a Horse. Square crown 8vo. with Illustrations, 14s.

STABLE PRACTICE; or, Hints on Training for the Turf, the Chase, and the Road. By CECIL. Fcp. 8vo. 5s.

STABLE TALK and TABLE TALK; or, Spectacles for Young Sportsmen. By HARRY HIEOVER. 2 vols. 8vo. 24s.

The HUNTING-FIELD. By HARRY HIEOVER. With Two Plates. Fcp. 8vo. 5s.

The POCKET and the STUD; or, Practical Hints on the Management of the Stable. By HARRY HIEOVER. Fcp. 8vo. 5s.

The STUD FARM; or, Hints on Breeding Horses for the Turf, the Chase, and the Road. By CECIL. Fcp. 8vo. 5s.

The STUD for PRACTICAL PURPOSES and PRACTICAL MEN: A Guide to the Choice of a Horse for Use more than for Show. By HARRY HIEOVER. Fcp. 8vo. 5s.

RECORDS of the CHASE, and MEMOIRS of CELEBRATED SPORTSMEN. By CECIL. With Two Plates by B. HERRING. Fcp. 8vo. 7s. 6d.

BLAINE'S ENCYCLOPÆDIA of RURAL SPORTS. *New Edition*; revised by HARRY HIEOVER, EPIHEMERA, and Mr. A. GRAHAM. With above 600 Woodcuts. 8vo. 50s.

HINTS on SHOOTING, FISHING, &c., both on SEA and LAND, and in the FRESH WATER LOCHS of SCOTLAND: Being the Experience of CHRISTOPHER IDLE, Esq. Fcp. 8vo. 5s.

Colonel HAWKER'S INSTRUCTIONS to YOUNG SPORTSMEN in all that relates to GUNS and SHOOTING. Tenth Edition, re-published by the Author's Son; with numerous Illustrations. 8vo. 21s.

London: LONGMAN, BROWN, GREEN, LONGMANS, and ROBERTS.
